Preface

This guide demonstrates how to handle sessions to permit single sign on and single log out in OpenAM client applications. This guide further demonstrates how to use the OpenAM APIs including both APIs for client applications, and also SPIs for authentication, policy, service management, delegation, and identity storage. Finally, this guide demonstrates how to write your own web policy agent.

1. Who Should Use this Guide

This guide is written for developers who adapt client applications to use OpenAM access management capabilities. It is also written for designers and developers extending and integrating OpenAM services for their organizations.

You do not need to be an OpenAM wizard to learn something from this guide, though a background in access management and developing web applications or developing for web and application servers can help. You can nevertheless get started with this guide, and then learn more as you go along.

2. Formatting Conventions

Some items are formatted differently from other text, like filenames, **commands**, and literal values.

```
$ echo Command line sessions are formatted with lines folded for easier reading.  
In HTML documents click the [-] image for a flat, copy-paste version. Click  
the [+] image for an expanded, line-wrapped version. > /dev/null
```

In many cases, sections pertaining to UNIX, GNU/Linux, Mac OS X, BSD, and so forth are marked (UNIX). Sections pertaining to Microsoft Windows might be marked (Windows). To avoid repetition, however, file system directory names are often given only in UNIX format as in /path/to/OpenAM, even if the text applies to C:\path\to\OpenAM as well.

Absolute path names usually begin with the placeholder /path/to/, which might translate to /opt/, C:\Program Files\, or somewhere else on your system. Unless you install from native packages, you create this location before you install.

```
class Test  
{  
    public static void main(String [] args)  
    {  
        System.out.println("This is a program listing.");  
    }  
}
```

3. Accessing OpenAM Documentation Online

Core documentation, such as what you are now reading, aims to be technically accurate and complete with respect to the software documented. Core documentation therefore follows a three-phase review process designed to eliminate errors. The review process should slow authors down enough that documentation you get with a stable release has had time to bake fully.

Fully baked core documentation is available at docs.forgerock.org.

The OpenAM Wiki regularly brings you more, fresh content. In addition, you are welcome to sign up and then edit the Wiki if you notice an error, or if you have something to share.

4. Joining the OpenAM Community

After you sign up at ForgeRock, you can also login to the Wiki and the issue database to follow what is happening with the project.

If you have questions regarding OpenAM which are not answered by the documentation, there is a mailing list which can be found at <https://lists.forgerock.org/mailman/listinfo/openam> where you are likely to find an answer. You can also make suggestions regarding updates at the documentation mailing list (<https://lists.forgerock.org/mailman/listinfo/docs>).

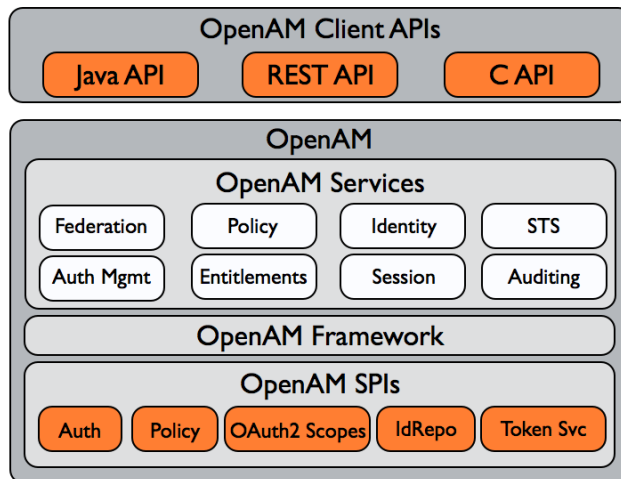

The Wiki has information on how to check out OpenAM source code. There is also a mailing list for OpenAM development that can be found at <https://lists.forgerock.org/mailman/listinfo/openam-dev>. Should you want to contribute a patch, test, or feature, or want to author part of the core documentation, first have a look on the ForgeRock site at how to get involved.

Chapter 1. OpenAM APIs and Protocols

Although policy agents and standards support make it possible for applications to use OpenAM for access management without changing your code, some deployments require tighter integration, or direct use of supported protocols and OpenAM APIs.

OpenAM supports a range of protocols and APIs that allow you not only to define specifically how access is managed in your client applications, but also to extend OpenAM capabilities to meet even those deployment requirements not yet covered in OpenAM.

This short chapter presents an overview of the APIs and protocols that OpenAM supports.

This guide primarily covers the OpenAM client APIs and SPIs, with emphasis on the Java APIs.

1.1. OpenAM APIs

OpenAM provides client application programming interfaces for a variety of needs.

- The OpenAM Java APIs provided through the OpenAM Java SDK let your Java and Java EE applications call on OpenAM for authentication, and authorization in both OpenAM and federated environments.

Detailed reference information is provided in the *OpenAM Java SDK API Specification*.

- The C SDK also provides APIs for native applications, such as new web server policy agents. The C SDK is delivered with OpenAM for Linux, Solaris, and Windows platforms.
- OpenAM exposes a RESTful API that can return JSON or XML over HTTP, allowing you to access authentication, authorization, and identity services from your web applications using REST clients in the language of your choice.

1.2. OpenAM SPIs

OpenAM provides Java based service provider interfaces to let you extend services for the requirements of your particular deployment.

Some examples of the plugins you can write follow in the list below. This guide demonstrates how to implement such plugins.

- Custom OAuth 2.0 scopes plugins define how OpenAM playing the role of authorization server handles scopes, including what token information to return regarding scopes set when authorization was granted.
- Custom authentication plugins let OpenAM authenticate users against a new authentication service or an authentication service specific to your deployment
- Post authentication plugins perform additional processing at the end of the authentication process, but before the subject is authenticated. Post authentication plugins can for example store information about the authentication in the user's profile, or call another system for audit logging purposes.
- Policy evaluation plugins implement new policy conditions, send attributes from the user profile as part of a policy response, extend the definition of the subjects to whom the policy applies, or customize how policy management is delegated.
- Identity repository plugins let OpenAM employ a new or custom user data store, other than a directory server or JDBC-accessible database.

Chapter 2. Developing Client Applications

Client applications access OpenAM services for authentication, authorization, and single sign on/single log out through the use of sessions. Client applications can also be allowed to manage authorization policies.

Client application integration with OpenAM can be coupled loosely, as in the case of an application running in a web server with an OpenAM policy agent to handle interaction with OpenAM service, more directly, as in the case where the client interacts with OpenAM over protocol, or tightly, as in the case of an application using the OpenAM Java or C API to interact with OpenAM services.

This part of the guide covers client interaction with OpenAM over supported protocols and using OpenAM APIs.

Chapter 3. Using RESTful Web Services

This chapter shows how to use the OpenAM RESTful interfaces for direct integration between web client applications and OpenAM.

3.1. About the RESTful API

OpenAM offers a RESTful API for these access and identity management operations:

- Authentication (login)
- Logout
- Token attribute retrieval
- Token validation
- Authorization
- OAuth 2.0 Authorization
- Logging
- Identity management (creating, reading, updating, deleting identities)
- Realm management (creating, reading, updating, deleting realms)

To call the API, access URLs under `identity/` where OpenAM is deployed, such as `https://openam.example.com:8443/openam/identity/`.

You can select the output format returned by specifying `json/` or `xml/` in the URL after `identity/`. For example, to return JSON, specify `https://openam.example.com:8443/openam/identity/json/`.

For the examples in this chapter, OpenAM has `c66Encode` for cookies activated. The encoding ensures that OpenAM tokens need not be percent encoded before being submitted with a request. Thus, an example token looks like this.

```
token.id=AQIC5wM2LY4SfczntBbXvEA0uECbqMY3J4NW3byH6xwgkGE.*AAJTSQACMDE.*
```

Without `c66Encode` activated, the same token might look like this.

```
token.id=AQIC5wM2LY4SfczntBbXvEA0uECbqMY3J4NW3byH6xwgkGE=@AAJTSQACMDE=#
```

In the latter example, you would have to percent encode the `=`, `@`, and `#` characters in your requests.

In this chapter, long URLs are wrapped to fit the printed page.

3.2. Authentication & Logout

Simple authentication with a user name and password returns a token.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate?
  username=bjensen
  &password=hifalutin"
token.id=AQIC5wM2LY4SfcxvdvH0XjtC_eWSs2RB54tgvgK8SuYi7aQ.*AAJTSQACMDE.*
```

If you must specify parameters as when authenticating to `/UI/Login`, you provide a percent encoded string of the parameters as the value of the `uri` parameter. The `/UI/Login` parameter deals with the realm, module, and service parameters. Setting the `client` parameter sets the user's IP address as part of the token following successful authentication. The default for the `client` parameter is the IP of the machine making the REST request.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate?
  username=bjensen
  &password=hifalutin
  &uri=realm%3D%2F%26module%3DDataStore
  &client=192.168.1.1"
token.id=AQIC5wM2LY4SfcxvdvH0XjtC_eWSs2RB54tgvgK8SuYi7aQ.*AAJTSQACMDE.*
```

You log out using the token to end the user session.

```
$ curl "https://openam.example.com:8443/openam/identity/logout?
  subjectid=AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*"
```

3.3. Token Validation & Attribute Retrieval

You check whether a token is valid as follows.

```
$ curl "https://openam.example.com:8443/openam/identity/isTokenValid?
  tokenid=AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*"
boolean=true
```

An invalid token returns `boolean=false`.

```
$ curl "https://openam.example.com:8443/openam/identity/isTokenValid?
  tokenid=INVALID"
boolean=false
```

With a valid token, you can retrieve attributes about the subject. OpenAM returns a series of *name, value* pairs.

```
$ curl "https://openam.example.com:8443/openam/identity/attributes?
  subjectid=AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*"
userdetails.token.id=
AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*
```

```
userdetails.attribute.name=uid
userdetails.attribute.value=bjensen
userdetails.attribute.name=mail
userdetails.attribute.value=bjensen@example.com
userdetails.attribute.name=sn
userdetails.attribute.value=Jensen
userdetails.attribute.name=userpassword
userdetails.attribute.value={SSHA}rhus0fYpkapDWEHcfT2Y7y83LMuC++F4Abqvig==
userdetails.attribute.name=cn
userdetails.attribute.value=Babs Jensen
userdetails.attribute.value=Barbara Jensen
userdetails.attribute.name=givename
userdetails.attribute.value=Barbara
userdetails.attribute.name=dn
userdetails.attribute.value=uid=bjensen,ou=people,dc=example,dc=com
userdetails.attribute.name=telephonenumber
userdetails.attribute.value=+1 408 555 1862
userdetails.attribute.name=objectclass
userdetails.attribute.value=organizationalPerson
userdetails.attribute.value=person
userdetails.attribute.value=posixAccount
userdetails.attribute.value=inetOrgPerson
userdetails.attribute.value=krbprincipalaux
userdetails.attribute.value=krbTicketPolicyAux
userdetails.attribute.value=top
```

You can specify attributes to limit what you retrieve.

```
$ curl "https://openam.example.com:8443/openam/identity/attributes?
subjectid=AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*
&attributenames=mail
&attributenames=uid"
userdetails.token.id=
AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*
userdetails.attribute.name=uid
userdetails.attribute.value=bjensen
userdetails.attribute.name=mail
userdetails.attribute.value=bjensen@example.com
```

When retrieving attributes, you can refresh the session thus setting the idle time to 0, by adding the boolean parameter `refresh=true` to the query string.

```
$ curl "https://openam.example.com:8443/openam/identity/attributes?
subjectid=AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*
&attributenames=cn
&refresh=true"
userdetails.token.id=
AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*
userdetails.attribute.name=cn
userdetails.attribute.value=Babs Jensen
userdetails.attribute.value=Barbara Jensen
```

3.4. Authorization

You can call on OpenAM to decide whether to authorize access to a protected resource based on a valid token. Of course, you must percent encode the resource URI.

```
$ curl "https://openam.example.com:8443/openam/identity/authorize?
uri=http%3A%2F%2Fwww.example.com%3A8080%2Fexamples%2Findex.html
&subjectid=AQIC5wM2LY4SfcxuxIP0VnP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*"
boolean=true
```

To indicate access denied, OpenAM returns `boolean=false`.

Additionally, you can access entitlements and entitlement policy decisions using the REST interface. In order to access the entitlements interface, you cannot however use the authentication token as is. Instead you must encode the token as performed in `Encoder.java`, and then URL-encode the result.

The entitlements REST interface uses the following path suffixes and query string parameters.

Path suffixes for entitlements include the following.

- `ws/1/entitlement/decision`: request a decision pertaining to a single resource
- `ws/1/entitlement/decisions`: request decisions pertaining to multiple resources
- `ws/1/entitlement/entitlement`: request decisions for a specified resource URL and all resources underneath

Query string parameters for entitlements include the following.

- `subject=encoded-token`, where the encoded token is as describe above.
- `action=get`, or `action=post`, which identifies the user agent action when requesting a decision.
- `application=iPlanetAMWebAgentService`
- `resource=resource-url`, or `multiple resources=resource-url` parameters for multiple decisions.
- `env=requestDnsName%3Dfqdn`, `env=requestIP%3Ddotted-quads`, `env=requestTime%3Dseconds-since-epoch`, and `env=requestDnsName%3Dtime-zone` where `time-zone` is from `Java TimeZone.getTimeZone().getID()`. The `env` parameters thus express conditions.

3.5. OAuth 2.0 Authorization

OpenAM exposes the following REST endpoints for different OAuth 2.0 purposes.

- Endpoints for OAuth 2.0 clients and resource servers, mostly defined in RFC 6749, *The OAuth 2.0 Authorization Framework*, with an additional tokeninfo endpoint useful to resource servers.
- An endpoint for OAuth 2.0 token administration. This is specific to OpenAM.
- An endpoint for OAuth 2.0 client administration. This is specific to OpenAM.

When accessing the APIs, browser-based REST clients can rely on OpenAM to handle the session as usual. First authenticate with OpenAM. Then perform the operations in the browser session.

Clients not running in a browser can authenticate as described in Section 3.2, “Authentication & Logout”, whereby OpenAM returns a token.id value. Clients pass the token.id value in a header named after the authentication cookie, by default iplanetDirectoryPro.

3.5.1. OAuth 2.0 Client & Resource Server Endpoints

As described in the *Administration Guide* chapter on *Managing OAuth 2.0 Authorization*, OpenAM exposes REST endpoints for making calls to OpenAM acting as an authorization server.

OpenAM OAuth 2.0 Endpoints

In addition to the standard authorization and token endpoints described in RFC 6749, OpenAM also exposes a token information endpoint for resource servers to get information about access tokens so they can determine how to respond to requests for protected resources. OpenAM as authorization server exposes the following endpoints for clients and resource servers.

/oauth2/authorize

Authorization endpoint defined in RFC 6749, used to obtain an authorization grant from the resource owner

Example: `https://openam.example.com:8443/openam/oauth2/authorize`

/oauth2/access_token

Token endpoint defined in RFC 6749, used to obtain an access token from the authorization server

Example: `https://openam.example.com:8443/openam/oauth2/access_token`

/oauth2/tokeninfo

Endpoint not defined in RFC 6749, used to validate tokens, and to retrieve information such as scopes

Given an access token, a resource server can perform an HTTP GET on `/oauth2/tokeninfo?access_token=token-id` to retrieve a JSON object indicating `token_type`, `expires_in`, `scope`, and the `access_token` ID.

Example: `https://openam.example.com:8443/openam/oauth2/tokeninfo`

The `/oauth2/authorize`, and `/oauth2/access_token` endpoints function as described in RFC 6749.

The `/oauth2/authorize` endpoint is protected by the policy created during OAuth 2.0 authorization server configuration, which grants all authenticated users access.

The `/oauth2/tokeninfo` endpoint takes an HTTP GET on `/oauth2/tokeninfo?access_token=token-id`, and returns information about the token.

Resource servers — or any party having the token ID — can get token information through this endpoint without authenticating. This means any application or user can validate the token without having to be registered with OpenAM.

The following example shows OpenAM issuing an access token, and then returning token information.

```
$ curl
--request POST
--user "myClientID:password"
--data "grant_type=password&username=demo&password=changeit&scope=cn%20mail"
https://openam.example.com:8443/openam/oauth2/access_token
{
  "expires_in": 599,
  "token_type": "Bearer",
  "refresh_token": "f6dcf133-f00b-4943-a8d4-ee939fc1bf29",
  "access_token": "f9063e26-3a29-41ec-86de-1d0d68aa85e9"
}
$ curl https://openam.example.com:8443/openam/oauth2/tokeninfo
?access_token=f9063e26-3a29-41ec-86de-1d0d68aa85e9
{
  "mail": "demo@example.com",
  "scope": [
    "mail",
    "cn"
  ],
  "cn": "demo",
  "realm": "/",
  "token_type": "Bearer",
  "expires_in": 577,
  "access_token": "f9063e26-3a29-41ec-86de-1d0d68aa85e9"
}
```

The resource server making decisions about whether the token is valid can thus use the `/oauth2/tokeninfo` endpoint to retrieve expiration information about the token. Depending on the scopes implementation, the JSON response about the token can also contain scope information. As described

in the *Administration Guide*, the default scopes implementation in OpenAM considers scopes to be names of attributes in the resource owner's user profile. Notice that the JSON response contains the values for those attributes from the user's profile, as in the preceding example, with scopes set to mail and cn.

3.5.2. OAuth 2.0 Token Administration Endpoint

The OpenAM-specific OAuth 2.0 token administration endpoint lets administrators read, list, and delete OAuth 2.0 tokens. OAuth 2.0 clients can also manage their own tokens.

Resource owners can manage OAuth 2.0 tokens that they authorized by using the web-based OAuth 2 Token Manager. See the *Administration Guide* section on *Managing OAuth 2.0 Tokens* for details.

OpenAM exposes the token administration endpoint at `/frrest/oauth2/token`, such as `https://openam.example.com:8443/openam/frrest/oauth2/token`.

Note

This endpoint location is likely to change in the future.

To get a token, perform an HTTP GET on `/frrest/oauth2/token/token-id`, as in the following example.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate?
username=amadmin&password=password"
token.id=AQIC5wM2LY4Sfcxs...EwNDU2NjE0*
$ curl
--request POST
--user "myClientID:password"
--data "grant_type=password&username=demo&password=changeit&scope=cn%20mail"
https://openam.example.com:8443/openam/oauth2/access_token
{
  "expires_in": 599,
  "token_type": "Bearer",
  "refresh_token": "f838e7d4-7e84-4743-af7c-9a9c42c2969e",
  "access_token": "9c6a48fc-44b1-4a0c-b4f0-672fba468b0f"
}
$ curl
--header "iplanetDirectoryPro: AQIC5wM2LY4Sfcxs...EwNDU2NjE0*"
https://openam.example.com:8443/openam/frrest/oauth2/token/9c6a48fc...fba468b0f
{
  "scope": [
    "mail",
    "cn"
  ],
  "type": [
    "access_token"
  ],
  "username": [
    "demo"
  ]
}
```

OAuth 2.0 Token Administration Endpoint

```
{
  "realm": [
    "/"
  ],
  "id": [
    "9c6a48fc-44b1-4a0c-b4f0-672fba468b0f"
  ],
  "parent": [
    "f838e7d4-7e84-4743-af7c-9a9c42c2969e"
  ],
  "expiry_time": [
    "1355741494888"
  ],
  "client_id": [
    "myClientID"
  ]
}
```

To list tokens, perform an HTTP GET on `/frrest/oauth2/token/?_query_id=conditions`, where *conditions* is a comma-separated list of *field=value* conditions. The *fields* are taken from the fields returned in the token object through this endpoint.

"expiry_time"

Token expiration time in milliseconds since 00:00:00 UTC, January 1, 1970.

"type"

Either "access_token" or "refresh_token".

"username"

OAuth 2.0 client to whom the token was issued.

"realm"

The realm for which the token was issued.

"id"

Unique ID of the token.

The following example shows a search for current access tokens that were issued to myClientID.

```
$ curl
--header "iplanetDirectoryPro: AQIC5wM2LY4Sfcxs...EwNDU2NjE0*"
https://openam.example.com:8443/openam/frrest/oauth2/token/?_queryID
=username%3DmyClientID%2Ctype%3Daccess_token
{
  "result": [
    {
      "scope": [
        "mail",
        "cn"
      ],
      "id": [
        "1b836369-4fcf-4fb2-b819-ee4b1314d4f1"
      ]
    }
  ]
}
```

OAuth 2.0 Token Administration Endpoint

```
    ],
    "type": [
      "access_token"
    ],
    "username": [
      "myClientID"
    ],
    "realm": [
      "/"
    ],
    "expiry_time": [
      "1355741986154"
    ]
  },
  {
    "scope": [
      "mail",
      "cn"
    ],
    "type": [
      "access_token"
    ],
    "username": [
      "myClientID"
    ],
    "realm": [
      "/"
    ],
    "id": [
      "5f1763fc-37ae-4698-9e84-d301d49e1f7e"
    ],
    "expiry_time": [
      "1355741982091"
    ]
  }
],
"pagedResultsCookie": null,
"remainingPagedResults": -1
}
```

To delete a token, perform an HTTP DELETE on `/frrest/oauth2/token/token-id`, as in the following example.

```
$ curl
--request POST
--data "grant_type=client_credentials&username=demo&password=changeit
&client_id=myClientID&client_secret=password&scope=cn%20mail"
https://openam.example.com:8443/openam/oauth2/access_token
{
  "expires_in": 599,
  "token_type": "Bearer",
  "access_token": "867aaab2-61d7-4b78-9b80-4f9098034540"
}
$ curl
--request DELETE
--header "iplanetDirectoryPro: AQIC5wM2LY4Sfcxs...EwNDU2NjE0*"
https://openam.example.com:8443/openam/frrest/oauth2/token/867aaab2..098034540
{
  "success": "true"
}
```

3.5.3. OAuth 2.0 Client Administration Endpoint

The OAuth 2.0 administration endpoint lets OpenAM administrators and agent administrators create (that is, register) and delete OAuth 2.0 clients.

OpenAM exposes this endpoint at `/frrest/oauth2/client`, such as `https://openam.example.com:8443/openam/frrest/oauth2/client`.

Note

This endpoint location is likely to change in the future.

To create an OAuth 2.0 client, perform an HTTP POST to `/frrest/oauth2/client/?_action=create` with a JSON object fully specifying the client, as in the following example.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5wM...3MTYxOA..*
$ curl --request POST --header "iplanetDirectoryPro: AQIC5wM...3MTYxOA..*"
--header "Content-Type: application/json"
--data '{"client_id":["testClient"],
      "realm":["/"],
      "userpassword":["secret12"],
      "com.forgerock.openam.oauth2provider.clientType":["Confidential"],
      "com.forgerock.openam.oauth2provider.redirectionURIs":
        ["www.client.com", "www.example.com"],
      "com.forgerock.openam.oauth2provider.scopes":["cn", "sn"],
      "com.forgerock.openam.oauth2provider.defaultScopes":["cn"],
      "com.forgerock.openam.oauth2provider.name":["My Test Client"],
      "com.forgerock.openam.oauth2provider.description":["OAuth 2.0 Client"]
    }'
http://openam.example.com:8080/openam/frrest/oauth2/client/?_action=create
{"success":"true"}
```

When creating an OAuth 2.0 client, use the following fields in your JSON object.

"client_id"

(Required) This field takes an array containing the client identifier as defined in RFC 6749.

"realm"

(Required) This field takes an array containing the OpenAM realm in which to create the client as defined in RFC 6749.

"userpassword"

(Required) This field takes an array containing the client secret as defined in RFC 6749.

"com.forgerock.openam.oauth2provider.clientType"

(Required) This field takes an array containing the client type, either "Confidential" or "Public" as defined in RFC 6749.

"com.forgerock.openam.oauth2provider.redirectionURIs"

(Optional for confidential clients) This field takes an array of client redirection endpoints as defined in RFC 6749.

"com.forgerock.openam.oauth2provider.scopes"

(Optional) This field takes an array of scopes as defined in RFC 6749. The default scopes implementation takes scopes to be names of attributes in the resource owner profile.

Specify localized scopes in *scope|locale|localized description* format.

"com.forgerock.openam.oauth2provider.defaultScopes"

(Optional) This field takes an array of default scopes set automatically when tokens are issued.

"com.forgerock.openam.oauth2provider.name"

(Optional) This field takes an array containing the client name to display to the resource owner when the resource owner must authorize client access to protected resources.

Specify localized names in *locale|localized name* format.

"com.forgerock.openam.oauth2provider.description"

(Optional) This field takes an array containing the description to display to the resource owner when the resource owner must authorize client access to protected resources.

Specify localized descriptions in *locale|localized description* format.

To delete an OAuth 2.0 client, perform an HTTP DELETE on `/frrest/oauth2/client/client-id`, as in the following example.

```
$ curl --request DELETE
--header "iplanetDirectoryPro: AQIC5wM...3MTYx0A.*"
https://openam.example.com:8443/openam/frrest/oauth2/client/testClient
{"success":"true"}
```

3.6. Logging

You can send OpenAM messages to log, specifying the message content and the log file in which to write your message.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate?
username=amadmin
&password=password"
token.id=AQIC5wM2LY4SfcwyCZkk-1JXzx6q1EzgagabHfBjMidb5jI.*AAJTSQACMDE.*
$ curl "https://openam.example.com:8443/openam/identity/log?
appid=AQIC5wM2LY4SfcwyCZkk-1JXzx6q1EzgagabHfBjMidb5jI.*AAJTSQACMDE.*
&subjectid=AQIC5wM2LY4SfcxuxIP0VnNP2lVjs7ypEM6VDx6srk56CN1Q.*AAJTSQACMDE.*
&logname=rest.access
&message=Hello%20World"
```

Logging takes a valid appid token for the subject with access to log the message, and also a subjectid token for the user whom the message concerns. If the tokens are valid and the access rights correct, your message ends up in the log specified.

```
$ cat openam/openam/log/rest.access
#Version: 1.0
#Fields: time Data LoginID ContextID IPAddr LogLevel Domain
LoggedBy MessageID ModuleName NameID HostName
"2011-09-14 16:38:17" /home/mark/openam/openam/log/
"cn=dsameuser,ou=DSAME Users,o=openam" aa307b2dcb721d4201
"Not Available" INFO o=openam "cn=dsameuser,ou=DSAME Users,o=openam"
LOG-1 rest.access "Not Available"192.168.56.2
"2011-09-14 16:38:17" "Hello World" id=bjensen,ou=user,o=openam
8a4025a2b3af291d01 "Not Available" INFO o=openam
id=amadmin,ou=user,o=openam "Not Available" rest.access "Not Available"
192.168.56.2
```

3.7. Identity Management

This section shows how to create, read, update, and delete identities using the RESTful APIs.

OpenAM has two REST APIs for managing identities.

- Under the `/json/users`, you find the newer JSON-based API.

Examples in this section show authentication using the API described in Section 3.2, “Authentication & Logout”. For browser-based clients, you can rely on OpenAM cookies rather than construct the header in your application.

The following sections cover this JSON-based API.

- Section 3.7.1, “Creating Identities”
- Section 3.7.2, “Reading Identities”
- Section 3.7.3, “Updating Identities”
- Section 3.7.4, “Deleting Identities”
- Under the `/identity` endpoint, you find the backwards-compatible, legacy API.

The following sections cover this backwards-compatible API.

- Section 3.7.5, “Creating Identities (Legacy API)”
- Section 3.7.6, “Reading & Searching for Identities (Legacy API)”
- Section 3.7.7, “Updating Identities (Legacy API)”

- Section 3.7.8, “Deleting Identities (Legacy API)”

3.7.1. Creating Identities

OpenAM lets administrators create a user profile by making an HTTP POST of the JSON representation of the profile to `/json/users/realm/?_action=create`. To add a user to the Top Level Realm, you do not need to specify the realm.

The following example shows an administrator creating a new user. The only required fields are name and userpassword. If no other name is provided, the entry you make for name defaults to both the user id and the user's last name.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --request POST --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
--header "Content-Type: application/json"
--data '{ "name": "bjensen", "userpassword": "secret12",
        "mail": "bjensen@example.com" }'
https://openam.example.com:8443/openam/json/users/?_action=create
{
  "name": "bjensen",
  "realm": "/",
  "uid": [
    "bjensen"
  ],
  "mail": [
    "bjensen@example.com"
  ],
  "sn": [
    "bjensen"
  ],
  "userpassword": [
    "{SSHA}0pXpKLPKCGY7g3YqZygJmKMw6IC2BLJimm1wg=="
  ],
  "cn": [
    "bjensen"
  ],
  "inetuserstatus": [
    "Active"
  ],
  "dn": [
    "uid=bjensen,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass": [
    "person",
    "sunIdentityServerLibertyPPService",
    "sunFederationManagerDataStore",
    "inetorgperson",
    "iPlanetPreferences",
    "iplanet-am-auth-configuration-service",
    "organizationalperson",
    "sunFMSAML2NameIdentifier",
    "inetuser",
    "iplanet-am-managed-person",
    "sunAMAuthAccountLockout",
    "iplanet-am-user-service",
    "top"
  ]
}
```

```
    },
    "universalid": [
      "id=bjensen,ou=user,dc=openam,dc=forgerock,dc=org"
    ]
  }
}
```

Alternatively, administrators can create user profiles with specific user IDs by doing an HTTP PUT of the JSON representation of the changes to `/json/users/user-id`, as shown in the following example.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --request PUT --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
--header "Content-Type: application/json"
--data '{ "userpassword": "secret12", "mail": "bjensen@example.com" }'
https://openam.example.com:8443/openam/json/users/bjensen
{
  "name": "bjensen",
  "realm": "/",
  "uid": [
    "bjensen"
  ],
  "mail": [
    "bjensen@example.com"
  ],
  "sn": [
    "bjensen"
  ],
  "userpassword": [
    "{SHA}e4DJoxvYVW/nsp62XJf29ZADE16YQgrxK+XuKA=="
  ],
  "cn": [
    "bjensen"
  ],
  "inetuserstatus": [
    "Active"
  ],
  "dn": [
    "uid=bjensen,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass": [
    "person",
    "sunIdentityServerLibertyPPService",
    "sunFederationManagerDataStore",
    "inetorgperson",
    "iPlanetPreferences",
    "iplanet-am-auth-configuration-service",
    "organizationalperson",
    "sunFMSAML2NameIdentifier",
    "inetuser",
    "iplanet-am-managed-person",
    "sunAMAuthAccountLockout",
    "iplanet-am-user-service",
    "top"
  ],
  "universalid": [
    "id=bjensen,ou=user,dc=openam,dc=forgerock,dc=org"
  ]
}
```

As shown in the examples, OpenAM returns the JSON representation of the profile on successful creation. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

3.7.2. Reading Identities

OpenAM lets users and administrators read profiles by requesting an HTTP GET on `/json/subrealm/users/user-id`. This allows users and administrators to verify user data, status, and directory. If users or administrators see missing or incorrect information, they can write down the correct information and add it using Section 3.7.3, “Updating Identities”. To read a profile on the Top Level Realm, you do not need to specify the realm.

Users can review the data associated with their accounts and administrators can read other user's profiles. The following example shows an administrator accessing user data. Users can view their information by changing `username=amadmin` to `user-id`.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
https://openam.example.com:8443/openam/json/users/demo
{
  "name": "demo",
  "realm": "/",
  "uid": [
    "demo"
  ],
  "sn": [
    "demo"
  ],
  "userpassword": [
    "{SSHA}S14oR2gusLWtiDKAS4twj63slXNNaMKpwr0Wdw=="
  ],
  "cn": [
    "demo"
  ],
  "inetuserstatus": [
    "Active"
  ],
  "dn": [
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass": [
    "person",
    "sunIdentityServerLibertyPPService",
    "sunFederationManagerDataStore",
    "inetorgperson",
    "iPlanetPreferences",
    "iplanet-am-auth-configuration-service",
    "organizationalperson",
    "sunFMSAML2NameIdentifier",
    "inetuser",
    "iplanet-am-managed-person",
    "sunAMAuthAccountLockout",
    "iplanet-am-user-service",
```

```
    "top"
  ],
  "universalid": [
    "id=demo,ou=user,dc=openam,dc=forgerock,dc=org"
  ]
}
```

As shown in the example, OpenAM returns the JSON representation of the profile on success. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

3.7.3. Updating Identities

OpenAM lets users update their own profiles, and lets administrators update other users' profiles. To update an identity do an HTTP PUT of the JSON representation of the changes to `/json/subrealm/users/user-id`. To update a profile on the Top Level Realm, you do not need to specify the realm.

The following example shows how users can update their own profiles.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=demo&password=changeit"
token.id=AQIC5...Y3MTAx*
$ curl --request PUT --header "iplanetDirectoryPro: AQIC5...Y3MTAx*"
--header "Content-Type: application/json"
--data '{ "mail": "demo@example.com" }'
https://openam.example.com:8443/openam/json/users/demo
{
  "name": "demo",
  "realm": "/",
  "uid": [
    "demo"
  ],
  "mail": [
    "demo@example.com"
  ],
  "sn": [
    "demo"
  ],
  "userpassword": [
    "{SHA}S14oR2gusLWtiDkAS4twj63sLXNNaMKpwr0Wdw=="
  ],
  "cn": [
    "demo"
  ],
  "inetuserstatus": [
    "Active"
  ],
  "dn": [
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass": [
    "person",
    "sunIdentityServerLibertyPPService",
    "sunFederationManagerDataStore",
    "inetorgperson",
    "iPlanetPreferences",
    "iplanet-am-auth-configuration-service",
```

```
    "organizationalperson",
    "sunFMSAML2NameIdentifier",
    "inetuser",
    "iplanet-am-managed-person",
    "sunAMAuthAccountLockout",
    "iplanet-am-user-service",
    "top"
  ],
  "universalid": [
    "id=demo,ou=user,dc=openam,dc=forgerock,dc=org"
  ]
}
```

As shown in the example, OpenAM returns the JSON representation of the profile on success. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

3.7.4. Deleting Identities

OpenAM lets administrators delete a user profile by making an HTTP DELETE call to `/json/subrealm/users/user-id`. To delete a user from the Top Level Realm, you do not need to specify the realm.

The following example removes a user from the top level realm. Only administrators should delete users. The user id is the only field required to delete a user.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --request DELETE --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
https://openam.example.com:8443/openam/json/users/bjensen
{"success": "true"}
```

On success, OpenAM returns a JSON object indicating success. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

3.7.5. Creating Identities (Legacy API)

OpenAM lets you create user profiles, and also create web and J2EE policy agent profiles. When you create an entry, you must provide the following parameters.

`admin`

Valid token for the user with permissions to add the identity

`identity_name`

A unique name for the identity to create

`identity_attribute_names`

LDAP attribute names for attributes to create

`identity_attribute_values_name`

LDAP attribute values for the identity to create. For example,
`identity_attribute_names=sn&identity_attribute_values_sn=Jensen.`

`identity_realm`

The realm in which to create the identity

`identity_type`

Either user or AgentOnly

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate?
  username=amadmin
  &password=password"
token.id=AQIC5wM2LY4SfcxSYA8eG-vrNHb_W7nG8XkfAGyRyuaebDY.*AAJTSQACMDE.*
$ curl "https://openam.example.com:8443/openam/identity/create?
  admin=AQIC5wM2LY4SfcxSYA8eG-vrNHb_W7nG8XkfAGyRyuaebDY.*AAJTSQACMDE.*
  &identity_name=testuser
  &identity_attribute_names=cn
  &identity_attribute_values_cn=Test%20User
  &identity_attribute_names=sn
  &identity_attribute_values_sn=User
  &identity_attribute_names=userpassword
  &identity_attribute_values_userpassword=secret12
  &identity_realm=%2F
  &identity_type=user"
```

3.7.6. Reading & Searching for Identities (Legacy API)

Reading is similar to attribute retrieval, as described in Section 3.3, “Token Validation & Attribute Retrieval”, but obtained using the token of a user with permissions to perform the search, as shown in the following example.

```
$ curl "https://openam.example.com:8443/openam/identity/read?
  admin=AQIC5wM2LY4SfcxSYA8eG-vrNHb_W7nG8XkfAGyRyuaebDY.*AAJTSQACMDE.*
  &name=testuser
  &attributes_names=realm
  &attributes_values_realm=%2F"
identitydetails.name=testuser
identitydetails.type=user
identitydetails.realm=o=openam
identitydetails.attribute=
identitydetails.attribute.name=uid
identitydetails.attribute.value=testuser
identitydetails.attribute=
identitydetails.attribute.name=sn
identitydetails.attribute.value=User
identitydetails.attribute=
identitydetails.attribute.name=userpassword
identitydetails.attribute.value={SHA}AzpT+N1sjrQhL1wfX2ETWh/Aqbd+lH9L0lhDqg==
identitydetails.attribute=
identitydetails.attribute.name=cn
identitydetails.attribute.value=Test User
identitydetails.attribute=
identitydetails.attribute.name=inetuserstatus
identitydetails.attribute.value=Active
identitydetails.attribute=
```

Updating Identities (Legacy API)

```
identitydetails.attribute.name=dn
identitydetails.attribute.value=uid=testuser,ou=people,dc=example,dc=com
identitydetails.attribute=
identitydetails.attribute.name=objectclass
identitydetails.attribute.value=person
identitydetails.attribute.value=sunIdentityServerLibertyPPService
identitydetails.attribute.value=inetorgperson
identitydetails.attribute.value=sunFederationManagerDataStore
identitydetails.attribute.value=iPlanetPreferences
identitydetails.attribute.value=iplanet-am-auth-configuration-service
identitydetails.attribute.value=organizationalperson
identitydetails.attribute.value=sunFMSAML2NameIdentifier
identitydetails.attribute.value=inetuser
identitydetails.attribute.value=iplanet-am-managed-person
identitydetails.attribute.value=iplanet-am-user-service
identitydetails.attribute.value=sunAMAuthAccountLockout
identitydetails.attribute.value=top
identitydetails.attribute=
identitydetails.attribute.name=universalid
identitydetails.attribute.value=id=testuser,ou=user,o=openam
```

You can search for user IDs by providing the following parameters.

admin

Valid token for the user with access to perform the search

attributes_names

LDAP attribute names for attributes to search

attributes_values_name

LDAP attribute values for the identity to search. For example,
attribute_names=sn&attributes_values_sn=Jensen.

filter

Additional LDAP filter component to limit the search results returned

```
$ curl "https://openam.example.com:8443/openam/identity/search?
admin=AQIC5wM2LY4SfcxSYA8eG-vrNHb_W7nG8XkfAGyRyuaebDY.*AAJTSQACMDE.*
&attributes_names=sn
&attributes_values_sn=Jensen
&attributes_names=mail
&attributes_values_mail=bjensen*
&attributes_names=realm
&attributes_values_realm=%2F"
string=bjensen
```

3.7.7. Updating Identities (Legacy API)

You can update an identity with the same parameters used to create identities, provided the token corresponds to a user with access to update the identity.

```
$ curl "https://openam.example.com:8443/openam/identity/update?
admin=AQIC5wM2LY4SfcxSYA8eG-vrNHb_W7nG8XkfAGyRyuaebDY.*AAJTSQACMDE.*
&identity_name=testuser"
```

Deleting Identities (Legacy API)

```
&identity_attribute_names=mail
&identity_attribute_values_mail=testuser%40example.com
&identity_realm=%2F
&identity_type=user"
```

3.7.8. Deleting Identities (Legacy API)

You can also delete an identity.

```
$ curl "https://openam.example.com:8443/openam/identity/delete?
admin=AQIC5wM2LY4SfcxSYA8eG-vrNHb_W7nG8XkfAGyRyuaebDY.*AAJTSQACMDE.*
&identity_name=testuser
&identity_realm=%2F
&identity_type=user"
```

3.8. Realm Management

This section shows how to create, read, update, and delete realms using the RESTful APIs.

- Under the `/json/realms` endpoint, you find the newer JSON-based API.

The following sections cover this JSON-based API.

- Section 3.8.1, “Default Parameters for Realms”
- Section 3.8.2, “Creating Realms”
- Section 3.8.3, “Reading Realms”
- Section 3.8.4, “Updating Realms”
- Section 3.8.5, “Deleting Realms”

3.8.1. Default Parameters for Realms

Realms have a number of fields entered with the default loading. The following table provides information on what the default realm settings are, and these settings can be updated, added, or deleted when updating a realm.

Table 3.1. Realm Parameters for JSON-based API

| Realm Parameter | Default | Purpose |
|-----------------------|---|---|
| realm | None - the only required field to add a realm | The name of the realm Example: testRealm |
| sunOrganizationStatus | None | The status of the realm Active or Inactive |

| Realm Parameter | Default | Purpose |
|------------------------|---|--|
| sunOrganizationAliases | None | Any applicable aliases associated with the realm. Be aware that an alias can only be used once. Entering an alias used by another realm will remove the alias from that realm and you will lose configuration. Example: openso.example.com |
| serviceNames | sunAMAuthHOTPService iPlanetAMAuthConfiguration sunAMAuthFederationService sunIdentityRepositoryService iPlanetAMPolicyConfigService iPlanetAMAuthService iPlanetAMAuthLDAPService sunAMAuthDataStoreService sunAMAuthSAEService sunAMDelegationService sunAMAuthWSSAuthModuleService iPlanetAMAuthOATHService | Services needed for the realm, including authentication modules |

3.8.2. Creating Realms

OpenAM lets administrators create a realm by making an HTTP POST of the JSON representation of the profile to `/json/realms/?_action=create`.

You can create realms using an HTTP POST of the JSON representation of the profile to `/json/realms/?_action=create`, as shown in the following example. The only required field is `realm`, but the realm will not be active if the status is not set.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --request POST --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
--header "Content-Type: application/json"
--data '{ "realm": "testRealm" }'
https://openam.example.com:8443/openam/json/realms/?_action=create
{"realmCreated":"/testRealm"}
```

You can also set the `sunOrganizationAliases` parameter, but it can only be assigned to one realm (usually the top level realm). Before setting this parameter, make sure it is not already assigned elsewhere. If you replace remove it from another realm, you will lose your configuration.

Alternatively, administrators can create realms by the specific realm name using the HTTP PUT of the JSON representation of the changes to `/json/realms/realm-id`, as shown in the following example.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --request PUT --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
--header "Content-Type: application/json"
--data '{ "sunOrganizationStatus": "Active" }'
https://openam.example.com:8443/openam/json/realms/testRealm
{
```

As shown in the examples, OpenAM returns the JSON representation of the profile on successful creation. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

3.8.3. Reading Realms

OpenAM lets administrators read realms by requesting an HTTP GET on `/json/realms/realm-id`. This allows administrators to review all active realm services for the realm, like policy configuration and modules. If users or administrators see missing information (such as Active status) or incorrect information, they can write down the correct information and add it using Section 3.8.4, “Updating Realms”

The following example shows an administrator receiving information about the `testRealm`.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
https://openam.example.com:8443/openam/json/realms/testRealm
{
  "serviceNames":[
    "sunAMAuthHOTPSERVICE",
    "iPlanetAMAuthConfiguration",
    "sunAMAuthFederationService",
    "sunIdentityRepositoryService",
    "iPlanetAMPolicyConfigService",
    "iPlanetAMAuthService",
    "iPlanetAMAuthLDAPService",
    "sunAMAuthDataStoreService",
    "sunAMAuthSAESERVICE",
    "sunAMDelegationService",
    "sunAMAuthWSSAuthModuleService",
    "iPlanetAMAuthOATHService"
  ]
}
```

As shown in the example, OpenAM returns the JSON representation of the profile on success. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

3.8.4. Updating Realms

OpenAM lets administrators update realms. To update a realm, do an HTTP PUT of the JSON representation of the changes to `/json/realms/realm-id`.

The following example shows how to update a realm.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5...Y3MTAx*
$ curl --request PUT --header "iplanetDirectoryPro: AQIC5...Y3MTAx*"
--header "Content-Type: application/json"
--data '{ "sunOrganizationStatus": "Active" }'
https://openam.example.com:8443/openam/json/realms/testRealm
```

As shown in the example, OpenAM returns the JSON representation of the profile on success. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

3.8.5. Deleting Realms

OpenAM lets administrators delete a realm by making an HTTP DELETE call to `/json/realms/realm-id`.

The following example deletes a realm. The top level realm cannot be deleted. Only administrators should delete realms. The name of the realm is the only field required to delete the realm.

Make sure that you do not have any information you need within a realm before deleting it. Once a realm is deleted, the only way to restore it is to return to a backed up deployment of OpenAM.

```
$ curl "https://openam.example.com:8443/openam/identity/authenticate
?username=amadmin&password=password"
token.id=AQIC5w...2NzEz*
$ curl --request DELETE --header "iplanetDirectoryPro: AQIC5w...2NzEz*"
https://openam.example.com:8443/openam/json/realms/testRealm
{"success":"true"}
```

On success, OpenAM returns a JSON object indicating success. On failure, OpenAM returns a JSON representation of the error including the HTTP status code.

Chapter 4. Using the OpenAM Java SDK

Important

This samples mentioned in this chapter are not available in the current release.

This chapter introduces OpenAM Java SDK. OpenAM Java SDK is delivered in the `samples/opensso-client.zip` where you unpacked the full version of OpenAM, such as `~/Downloads/opensso/samples/opensso-client.zip`. To prepare to install the OpenAM Java SDK, first unzip `opensso-client.zip`.

```
$ mkdir -p /path/to/openam-client ; cd /path/to/openam-client
$ unzip ~/Downloads/opensso/samples/opensso-client.zip
```

As a result, you have two directories that include the SDK and also sample command-line and web-based client applications.

`src/`

This directory contains the SDK and client sample commands.

- `classes/`: compiled samples
- `lib/`: SDK and required libraries
- `resources/`: properties configuration for the SDK and samples
- `scripts/`: installation scripts and scripts to run the samples on UNIX, Linux, and Windows systems
- `sources/`: sample code

`war/`

This directory contains a web application archive with client samples accessible through the browser after you install the `.war` in a web application container.

Procedure 4.1. To Install OpenAM SDK Command-Line Examples

The command-line samples access OpenAM over HTTP or HTTPS.

1. Compile the samples.

```
$ cd sdk/
$ chmod +x scripts/*.sh
$ ./scripts/compile-samples.sh
```

2. Set up the samples to connect to OpenAM.

```
$ mkdir /path/to/openam-client/debug
$ ./scripts/setup.sh
```

```

Debug directory (make sure this directory exists): /path/to/openam-client/debug
Application user (e.g. URLAccessAgent) password: secret12
Protocol of the server: http
Host name of the server: openam.example.com
Port of the server: 8080
Server's deployment URI: openam
Naming URL (hit enter to accept default value,
http://openam.example.com:8080/openam/namingservice):
$

```

This sets up the configuration file for the samples, resources/AMConfig.properties. Read the comments in the file to see the configuration settings, many of which are similar to those used by OpenAM on the server side.

3. Check that the login sample works.

```

$ ./scripts/Login.sh
Realm (e.g. /):
Login module name (e.g. DataStore or LDAP): DataStore
Login locale (e.g. en_US or fr_FR): en_US
DataStore: Obtained login context
User Name: amadmin
Password: password
Login succeeded.
Logged Out!!

```

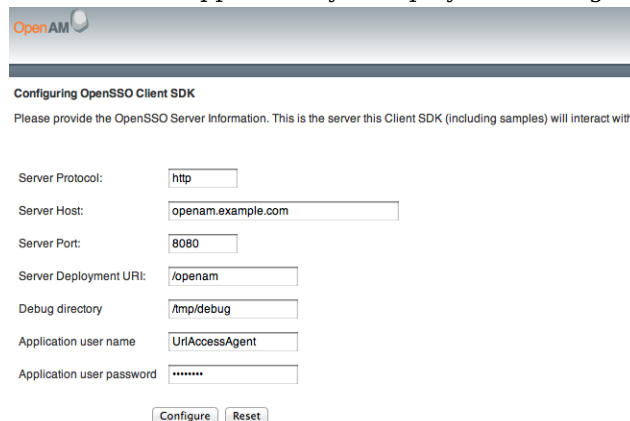

Procedure 4.2. To Install OpenAM SDK Web-Based Samples

The web-based samples also access OpenAM over HTTP or HTTPS.

1. Deploy the web application.

```
$ mv war/opensso-client-jdk15.war /path/to/tomcat/webapps/openam-client.war
```

2. Browse to the application you deployed to configure access to OpenAM.

The screenshot shows the OpenAM logo at the top left. Below it, the title "Configuring OpenSSO Client SDK" is displayed. A message states: "Please provide the OpenSSO Server Information. This is the server this Client SDK (including samples) will interact with." The form contains several input fields with labels and values:

- Server Protocol: http
- Server Host: openam.example.com
- Server Port: 8080
- Server Deployment URI: /openam
- Debug directory: /tmp/debug
- Application user name: UrlAccessAgent
- Application user password: (masked with dots)

At the bottom of the form, there are two buttons: "Configure" and "Reset".

Use the following hints to complete the configuration.

Server Protocol

Protocol to access OpenAM (http or https)

Server Host

Fully qualified domain name for OpenAM, such as `openam.example.com`

Server Port

OpenAM port number such as 8080 or 8443

Server Deployment URI

URI entry point to OpenAM such as `/openam`

Debug directory

Where to write the debug messages for the client samples

Application user name

An user agent configured to access OpenAM, such as `UrlAccessAgent` set up when OpenAM was installed

Application user password

The user agent password

3. After successful configuration, click the link to return to the URL where you deployed the application to view the available sample clients.

Chapter 5. Authenticating Using OpenAM Java SDK

This chapter looks at authentication with the OpenAM Java SDK and at the sample client, `Login.java`, which demonstrates authenticating to OpenAM from a client application, provided a realm, user name, and password.

With OpenAM, your client application performs the following steps to handle authentication.

1. Sets up an `AuthContext`, based on the realm in which the user authenticates.
2. Starts the login process by calling the `AuthContext login()` method.
3. Handling authentication callbacks to retrieve credentials from the user who is authenticating.

Your application loops through the authentication callbacks by using the `AuthContext getRequirements()` and `hasMoreRequirements()` methods. Each time it finishes populating a callback with the credentials retrieved, your application calls `submitRequirements()` to send the credentials to OpenAM's Authentication Service.

4. After handling all authentication callbacks, your application calls the `AuthContext getStatus()` method.

On login success, OpenAM sets up an `SSOToken` that holds information about the authentication, and also about the user's environment and session.

5. When the user logs out, your application can end the session by calling the `AuthContext logout()` method.

The `AuthContext` class is provided by the `com.sun.identity.authentication` package, part of the OpenAM client API. Callback classes are provided by the `javax.security.auth.callback` package, which provides callbacks for choices, confirmations, locales, names, passwords, text input, and text output.

See the *OpenAM Java SDK API Specification* for reference.

As the sample client gets the realm (called `organization` in the sample), locale, and authentication module to set up the authentication context, there is not need for a language callback to get the local afterwards. The `Login.java` example does, however, show simple ways of handling callbacks for the command-line context. The implementation of the sample client follows.

```
package com.sun.identity.samples.authentication;
```

```

import java.io.BufferedReader;
import java.io.InputStreamReader;
import java.io.IOException;
import javax.security.auth.callback.Callback;
import javax.security.auth.callback.ChoiceCallback;
import javax.security.auth.callback.NameCallback;
import javax.security.auth.callback.PasswordCallback;
import javax.security.auth.callback.TextInputCallback;
import javax.security.auth.callback.TextOutputCallback;
import javax.security.auth.callback.UnsupportedCallbackException;
import com.sun.identity.authentication.AuthContext;
import com.sun.identity.authentication.spi.AuthLoginException;
import com.sun.identity.shared.debug.Debug;

public class Login {
    private String loginIndexName;
    private String orgName;
    private String locale;

    private Login(String loginIndexName, String orgName) {
        this.loginIndexName = loginIndexName;
        this.orgName = orgName;
    }

    private Login(String loginIndexName, String orgName, String locale) {
        this.loginIndexName = loginIndexName;
        this.orgName = orgName;
        this.locale = locale;
    }

    protected AuthContext getAuthContext()
        throws AuthLoginException {
        AuthContext lc = new AuthContext(orgName);
        AuthContext.IndexType indexType = AuthContext.IndexType.MODULE_INSTANCE;
        if (locale == null || locale.length() == 0) {
            lc.login(indexType, loginIndexName);
        } else {
            lc.login(indexType, loginIndexName, locale);
        }
        debugMessage(loginIndexName + ": Obtained login context");
        return lc;
    }

    private void addLoginCallbackMessage(Callback[] callbacks)
        throws UnsupportedCallbackException {
        int i = 0;
        try {
            for (i = 0; i < callbacks.length; i++) {
                if (callbacks[i] instanceof TextOutputCallback) {
                    handleTextOutputCallback((TextOutputCallback)callbacks[i]);
                } else if (callbacks[i] instanceof NameCallback) {
                    handleNameCallback((NameCallback)callbacks[i]);
                } else if (callbacks[i] instanceof PasswordCallback) {
                    handlePasswordCallback((PasswordCallback)callbacks[i]);
                } else if (callbacks[i] instanceof TextInputCallback) {
                    handleTextInputCallback((TextInputCallback)callbacks[i]);
                } else if (callbacks[i] instanceof ChoiceCallback) {
                    handleChoiceCallback((ChoiceCallback)callbacks[i]);
                }
            }
        } catch (IOException e) {
            e.printStackTrace();
        }
    }

```

```

        throw new UnsupportedOperationException(callbacks[i], e.getMessage());
    }
}

private void handleTextOutputCallback(TextOutputCallback toc) {
    debugMessage("Got TextOutputCallback");
    // display the message according to the specified type

    switch (toc.getMessageType()) {
        case TextOutputCallback.INFORMATION:
            debugMessage(toc.getMessage());
            break;
        case TextOutputCallback.ERROR:
            debugMessage("ERROR: " + toc.getMessage());
            break;

            debugMessage("WARNING: " + toc.getMessage());
            break;
        default:
            debugMessage("Unsupported message type: " +
                toc.getMessageType());
    }
}

private void handleNameCallback(NameCallback nc)
    throws IOException {
    // prompt the user for a username
    System.out.print(nc.getPrompt());
    System.out.flush();
    nc.setName((new BufferedReader
        (new InputStreamReader(System.in))).readLine());
}

private void handleTextInputCallback(TextInputCallback tic)
    throws IOException {
    // prompt for text input
    System.out.print(tic.getPrompt());
    System.out.flush();
    tic.setText((new BufferedReader
        (new InputStreamReader(System.in))).readLine());
}

private void handlePasswordCallback>PasswordCallback pc)
    throws IOException {
    // prompt the user for sensitive information
    System.out.print(pc.getPrompt());
    System.out.flush();
    String passwd = (new BufferedReader(new InputStreamReader(System.in))).
        readLine();
    pc.setPassword(passwd.toCharArray());
}

private void handleChoiceCallback(ChoiceCallback cc)
    throws IOException {
    // ignore the provided default value
    System.out.print(cc.getPrompt());

    String[] strChoices = cc.getChoices();
    for (int j = 0; j < strChoices.length; j++) {
        System.out.print("choice[" + j + "] : " + strChoices[j]);
    }
    System.out.flush();
}

```

```

        cc.setSelectedIndex(Integer.parseInt((new BufferedReader(
            (new InputStreamReader(System.in))).readLine())));
    }

    protected boolean login(AuthContext lc)
        throws UnsupportedOperationException {
        boolean succeed = false;
        Callback[] callbacks = null;

        // get information requested from module
        while (lc.hasMoreRequirements()) {
            callbacks = lc.getRequirements();
            if (callbacks != null) {
                addLoginCallbackMessage(callbacks);
                lc.submitRequirements(callbacks);
            }
        }

        if (lc.getStatus() == AuthContext.Status.SUCCESS) {
            System.out.println("Login succeeded.");
            succeed = true;
        } else if (lc.getStatus() == AuthContext.Status.FAILED) {
            System.out.println("Login failed.");
        } else {
            System.out.println("Unknown status: " + lc.getStatus());
        }

        return succeed;
    }

    protected void logout(AuthContext lc)
        throws AuthLoginException {
        lc.logout();
        System.out.println("Logged Out!!");
    }

    static void debugMessage(String msg) {
        System.out.println(msg);
    }

    public static void main(String[] args) {
        try {
            System.out.print("Realm (e.g. /): ");
            String orgName = (new BufferedReader(
                new InputStreamReader(System.in))).readLine();

            System.out.print("Login module name (e.g. DataStore or LDAP): ");
            String moduleName = (new BufferedReader(
                new InputStreamReader(System.in))).readLine();

            System.out.print("Login locale (e.g. en_US or fr_FR): ");
            String locale = (new BufferedReader(
                new InputStreamReader(System.in))).readLine();

            Login login = new Login(moduleName, orgName, locale);
            AuthContext lc = login.getAuthContext();
            if (login.login(lc)) {
                login.logout(lc);
            }
        } catch (IOException e) {
            e.printStackTrace();
        } catch (AuthLoginException e) {

```

```
        e.printStackTrace();
    } catch (UnsupportedCallbackException e) {
        e.printStackTrace();
    }
    System.exit(0);
}
```

For instructions on building the sample clients, see the chapter *Using the OpenAM Java SDK*.

Chapter 6. Handling Single Sign On Using OpenAM Java SDK

Important

This samples mentioned in this chapter are not available in the current release.

This chapter looks at handling session tokens with the OpenAM Java SDK using the sample client `SSOTokenSample.java`.

When a user authenticates successfully, OpenAM sets up a single sign on session for the user. The session is associated with an SSO token that holds information about the authentication, and also about the user's environment and session. OpenAM disposes of the session when the authentication context `logout()` method is called, or when a session timeout is reached. At that point the SSO token is no longer valid.

When your application has an `AuthContext` after successful authentication, you can retrieve the SSO token from the context. You also can get the token as shown in the sample client by passing an SSO token ID from OpenAM to an `SSOTokenManager`.

If your application needs to be notified of changes, you can register an `SSOTokenListener` on the token by using the token's `addSSOTokenListener()` method. OpenAM then calls your `SSOTokenListener ssoTokenChanged()` method when the session times out, is disposed of, or has a property that changes.

The sample client takes an SSO token ID to get the token from OpenAM, and then displays some information from the SSO token. The implementation of the sample client follows.

```
package com.sun.identity.samples.sso;

import java.io.BufferedReader;
import java.io.InputStreamReader;
import java.io.IOException;
import java.net.InetAddress;
import com.iplanet.sso.SSOException;
import com.iplanet.sso.SSOToken;
import com.iplanet.sso.SSOTokenID;
import com.iplanet.sso.SSOTokenManager;

public class SSOTokenSample {
    private SSOTokenManager manager;
    private SSOToken token;

    private SSOTokenSample(String tokenID)
        throws SSOException
    {
        if (validateToken(tokenID)) {
            setGetProperties(token);
        }
    }
}
```

```

    }
}

private boolean validateToken(String tokenID)
    throws SS0Exception
{
    boolean validated = false;
    manager = SS0TokenManager.getInstance();
    token = manager.createSS0Token(tokenID);

    // isValid method returns true for valid token.
    if (manager.isValidToken(token)) {
        // let us get all the values from the token
        String host = token.getHostName();
        java.security.Principal principal = token.getPrincipal();
        String authType = token.getAuthType();
        int level = token.getAuthLevel();
        InetAddress ipAddress = token.getIPAddress();
        long maxTime = token.getMaxSessionTime();
        long idleTime = token.getIdleTime();
        long maxIdleTime = token.getMaxIdleTime();

        System.out.println("SS0Token host name: " + host);
        System.out.println("SS0Token Principal name: " +
            principal.getName());
        System.out.println("Authentication type used: " + authType);
        System.out.println("IPAddress of the host: " +
            ipAddress.getHostAddress());
        validated = true;
    }

    return validated;
}

private void setGetProperties(SS0Token token)
    throws SS0Exception
{
    /*
     * Validate the token again, with another method
     * if token is invalid, this method throws an exception
     */
    manager.validateToken(token);
    System.out.println("SS0 Token validation test Succeeded.");

    // Get the SS0TokenID associated with the token and print it.
    SS0TokenID id = token.getTokenID();
    String tokenId = id.toString();
    System.out.println("Token ID: " + tokenId);

    // Set and get properties in the token.
    token.setProperty("TimeZone", "PST");
    token.setProperty("County", "SantaClara");
    String tZone = token.getProperty("TimeZone");
    String county = token.getProperty("County");

    System.out.println("Property: TimeZone: " + tZone);
    System.out.println("Property: County: " + county);
}

public static void main(String[] args) {
    try {
        System.out.print("Enter SS0Token ID: ");
    }
}

```

```
        String ssoTokenID = (new BufferedReader(
            new InputStreamReader(System.in))).readLine();
        new SSOTokenSample(ssoTokenID.trim());
    } catch (SSOException e) {
        e.printStackTrace();
    } catch (IOException e) {
        e.printStackTrace();
    }
    System.exit(0);
}
}
```

Before you run the script that calls the sample, authenticate to OpenAM in order to have OpenAM generate the SSO token ID. To see the SSO token ID, you can either authenticate on the command line using the RESTful authenticate command, or alternatively run the `SSOTokenSampleServlet` web-based sample.

```
$ scripts/SSOTokenSample.sh
Enter SSOToken ID:
  AQIC5wM2LY4SfcxsdrU55RwePLUIbY8xTjeHf3Xnw6hph0E.*AAJTSQACMDE.*
SSOToken host name: 192.168.56.1
SSOToken Principal name:
  id=bjensen,ou=user,o=realm,ou=services,dc=openam,dc=forgerock,dc=org
Authentication type used: DataStore
IPAddress of the host: 192.168.56.1
SSO Token validation test Succeeded.
Token ID: AQIC5wM2LY4SfcxsdrU55RwePLUIbY8xTjeHf3Xnw6hph0E.*AAJTSQACMDE.*
Property: TimeZone: PST
Property: County: SantaClara
```

Notice both the properties populated by OpenAM, and also the two properties, `TimeZone` and `County`, that are set by the sample client.

6.1. Receiving Notifications

If your application implements a listener for change notification, such as a `SessionListener` to handle notification when a session is invalidated, then you must configure the following settings in the `AMConfig.properties` configuration file for your application.

`com.ipianet.am.notification.url`
Set this parameter to `http://host:port/context/notificationservice`.

`com.ipianet.am.sdk.caching.enabled`
Set this parameter to `true`.

`com.ipianet.am.serverMode`
Set this parameter to `false`.

`com.sun.identity.client.notification.url`
Set this parameter to `http://host:port/context/notificationservice`.

`com.sun.identity.idm.cache.enabled`

Set this parameter to `true`.

`com.sun.identity.idm.remote.notification.enabled`

Set this parameter to `true`.

`com.sun.identity.sm.cache.enabled`

Set this parameter to `true`.

`com.sun.identity.sm.enableDataStoreNotification`

Set this parameter to `true`.

The above configuration to access the notification service also applies for other types of listeners, such as `ServiceListener`, and `IdEventListener` implementations. See the *OpenAM Java SDK API Specification* for details on the available listener interfaces.

Chapter 7. Requesting Policy Decisions Using OpenAM Java SDK

Important

This samples mentioned in this chapter are not available in the current release.

This chapter shows how to request policy decision by using OpenAM Java SDK. The chapter focuses on the sample client, `PolicyEvaluationSample.java`, which demonstrates making a request to OpenAM for a policy decision about access to a web resource.

OpenAM centralizes policy administration, policy evaluation, and policy decision making so that your applications do not have to do so. In many deployments, OpenAM policy agents and the Open Identity gateway can handle policy enforcement independently from your application code.

If your application does need to request a policy decision from OpenAM, then your application can retrieve a `PolicyEvaluator` from a client-side `PolicyEvaluatorFactory`, and then call the `PolicyEvaluator.getPolicyDecision()` method. For boolean decisions such as allow or deny, your application can also call the `isAllowed()` method.

To make a policy decision, OpenAM needs an `SSOToken`, the resource to access, the action the user wants to perform on the resource such as HTTP GET or POST, and a `Map` of environment settings you can use to specify conditions and attributes in the session or can pass back as an empty `Map` if your policy does not include conditions and response attributes.

The `PolicyEvaluationSample` class takes as its configuration the user credentials, service name, resource, and action that you provide in a Java properties file. It then authenticates the user to get an `SSOToken` using the `TokenUtils.java` helper methods. At that point it has sufficient information to request a policy decision.

The implementation of the sample client follows.

```
package samples.policy;

import com.iplanet.sso.SSOToken;
import com.iplanet.sso.SSOTokenManager;

        String userName, String password) throws Exception {
        System.out.println("Entering getSSOToken():"
            + "userName=" + userName + ","
            + "password=" + password);
        SSOToken ssoToken = TokenUtils.getSessionToken("/",
            userName, password);
        System.out.println("TokenID:" + ssoToken.getTokenID().toString());
        System.out.println("returning from getSSOToken()");
        return ssoToken;
    }

    private void getPolicyDecision(
        SSOToken ssoToken,
        String serviceName,
        String resourceName,
        String actionName)
        throws Exception {
        System.out.println("Entering getPolicyDecision():"
            + "resourceName=" + resourceName + ","
            + "serviceName=" + serviceName + ",");
    }
}

```

```

        + "actionName=" + actionName);
PolicyEvaluator pe = PolicyEvaluatorFactory.getInstance().
    getPolicyEvaluator(serviceName);

Map env = new HashMap();
Set attrSet = new HashSet();
Set actions = new HashSet();
actions.add(actionName);
PolicyDecision pd = pe.getPolicyDecision(ssoToken, resourceName,
    actions, env);
System.out.println("policyDecision:" + pd.toXML());

System.out.println("returning from getPolicyDecision()");
}

private Properties getProperties(String file)
throws MissingResourceException {
    Properties properties = new Properties();
    ResourceBundle bundle = ResourceBundle.getBundle(file);
    Enumeration e = bundle.getKeys();
    System.out.println("sample properties:");
    while (e.hasMoreElements()) {
        String key = (String) e.nextElement();
        String value = bundle.getString(key);
        properties.put(key, value);
        System.out.println(key + ":" + value);
    }
    return properties;
}
}

```

Before you run the script that calls the sample, edit the properties file, `resources/policyEvaluationSample.properties`, to indicate the user credentials, resource to access, and HTTP method to use. You can use a resource that might not exist for the purposes of this example.

```

user.name=demo
user.password=changeit
service.name=iPlanetAMWebAgentService
resource.name=http://www.example.com:80/banner.html
action.name=GET

```

Also, set up a policy in OpenAM that corresponds to the resource in question. You can set up the policy in OpenAM console under Access Control > *Realm Name* > Policies. Concerning the *Realm Name*, notice that unless you change the code, the sample uses the top-level realm, `/` to authenticate the user.

With the properties configured and policy in place, get the decision from OpenAM using the script, `scripts/run-policy-evaluation-sample.sh`.

```

$ scripts/run-policy-evaluation-sample.sh
Using properties file:policyEvaluationSample
sample properties:
user.password:changeit
service.name:iPlanetAMWebAgentService
user.name:demo
resource.name:http://www.example.com:80/banner.html

```

```
action.name:GET
-----:
Entering getSSOToken():userName=demo,password=changeit
TokenID:AQIC5wM2LY4Sfcwu-JzDtYKCaxP-DxROXYd73zLlDt3fCh4.*AAJTSQACMDE.*
returning from getSSOToken()
Entering getPolicyDecision():
  resourceName=http://www.example.com:80/banner.html,
  serviceName=iPlanetAMWebAgentService,
  actionName=GET
policyDecision:<PolicyDecision>
<ResponseAttributes>
</ResponseAttributes>
<ActionDecision timeToLive="9223372036854775807">
<AttributeValuePair>
<Attribute name="GET"/>
<Value>allow</Value>
</AttributeValuePair>
<Advices>
</Advices>
</ActionDecision>
</PolicyDecision>

returning from getPolicyDecision()
```

As you see, the policy decision response is formatted here as an XML document.¹ Notice here the line showing that OpenAM has allowed access to the resource.

```
<Value>allow</Value>
```

¹The PolicyDecision element is defined in *openam*/WEB-INF/remoteInterface.dtd where *openam* is the location where the OpenAM web application is deployed.

Chapter 8. Using Fedlets in Java Web Applications

This chapter introduces OpenAM Fedlets, and shows how to use the Fedlet as part of your Java web application.

An OpenAM *Fedlet* is a small web application that can do federation in your service provider application with OpenAM acting as the identity provider. The Fedlet does not require an entire OpenAM installation alongside your application, but instead can redirect to OpenAM for single sign on, and to retrieve SAML assertions.

Procedure 8.1. To Create a Fedlet

The OpenAM administrator running the identity provider server creates a Fedlet.zip file for your service provider application, and then sends you the .zip.

1. Before creating the Fedlet, create a Hosted Identity Provider if you have not already done so.
2. On the Common Tasks page of the OpenAM console, click Create Fedlet.
3. Note that the Circle of Trust includes your hosted identity provider, and that Identity Provider is set to your to hosted identity provider.
4. Name the Fedlet, and also set the Destination URL.

You can use the deployment URL, such as `http://www.example.com:8080/fedlet` as both the name and the destination URL.

5. If you must map attributes to match profiles on the service provider, set up the attribute mapping.

To prepare to perform the Fedlet Attribute Query example, set `CommonName=cn`, `GivenName=sn`, and `UserStatus=inetUserStatus`.

6. Click create to generate the Fedlet.zip file, such as `$HOME/openam/myfedlets/httpwwwexamplecom8080fedlet/Fedlet.zip`.
7. Provide the Fedlet to the service provider.

Procedure 8.2. To Install the Fedlet as a Demo Application

Fedlet.zip includes the fedlet.war archive corresponding to the identity provider, and a README file.

- The `fedlet.war` archive contains both the Fedlet as a demo web application, and also the files you use to include the Fedlet in your service provider application.
- The README file describes how to use the Fedlet.

1. Deploy the Fedlet in your web container.

```
$ unzip Fedlet.zip
$ mv fedlet.war /path/to/tomcat/webapps
```

2. Browse to the Fedlet URL, and then click the links to set up the configuration directory in `$HOME/fedlet`, where `$HOME` corresponds to the user running the web application container.
3. In the Fedlet configuration directory, set up a JKS keystore file, keystore password file, and key password file.

For demo purposes, you can copy the test `keystore.jks`, `.keypass`, and `.storepass` from the OpenAM identity provider.

```
$ cd /home/user/openam/openam
$ scp keystore.jks .keypass .storepass www.example.com:/home/user/fedlet/
user@www.example.com's password:
keystore.jks                100% 1348    1.3KB/s   00:00
.keypass                    100%   36     0.0KB/s   00:00
.storepass                   100%   36     0.0KB/s   00:00
```

4. Try one or more examples from the Fedlet home page to validate Fedlet setup.

OpenAM

Validate Fedlet Setup

Click following links to start Fedlet(SP) and/or IDP initiated Single Sign-On. Upon successful completion, you will be presented with a page to display the Single Sign-On Response, Assertion and AttributeStatement received from IDP side.

Fedlet (SP) Configuration Directory: `/home/mark/fedlet`
Fedlet (SP) Entity ID: `http://www.example.com:8080/fedlet`
IDP Entity ID: `http://openam-ter.example.com:8080/openam`

[Run Fedlet \(SP\) initiated Single Sign-On using HTTP POST binding](#)
[Run Fedlet \(SP\) initiated Single Sign-On using HTTP Artifact binding](#)
[Run Identity Provider initiated Single Sign-On using HTTP POST binding](#)
[Run Identity Provider initiated Single Sign-On using HTTP Artifact binding](#)

After setting up OpenAM with the default subjects, you can login on the identity provider with user name `demo` and password `changeit`.

Procedure 8.3. To Add Your Application

The Fedlet includes the following files that you use when building your own service provider application based on the demo web application, including a set of JavaServer Pages (JSP) examples.

conf/

Configuration files copied to \$HOME/fedlet when you first deploy and configure the Fedlet. When deploying your application, you can move these to an alternate location passed to the Java virtual machine for the web application container at startup. For example, if you store the configuration under /export/fedlet/, then you could pass the following property to the JVM.

```
-Dcom.sun.identity.fedlet.home=/export/fedlet/conf
```

You do not need to include these files in your application.

fedletAttrQuery.jsp

fedletAttrResp.jsp

Sample SAML attribute query and response handlers. See the Fedlet README file for more information.

fedletEncode.jsp

Utility JSP to encode a password, such as the password used to protect a Java keystore

fedletSampleApp.jsp

index.jsp

Demo application. You can remove these before deployment to replace them with your application.

fedletXACMLQuery.jsp

fedletXACMLResp.jsp

Sample SAML XACML query and response handlers. See the Fedlet README file for more information.

logout.jsp

Utility page to perform single log out

saml2/jsp/

JSPs to initiate single sign on and single logout, and to handle error, and also a JSP for obtaining Fedlet metadata, `saml2/jsp/exportmetadata.jsp`

WEB-INF/classes/

Localized Java properties files for strings used in the Fedlet user interface

WEB-INF/lib/

Fedlet libraries required by your application

WEB-INF/web.xml

Fedlet web application configuration, showing how JSPs map to URLs used in the Fedlet. Add mappings for your application before deployment.

In the web.xml mappings, your application must be mapped to /fedletapplication, as this is the assertion consumer URL set in the Fedlet metadata.

```
<servlet>
  <servlet-name>yourApp</servlet-name>
  <jsp-file>/fedletSampleApp.jsp</jsp-file>
</servlet>
<servlet-mapping>
  <servlet-name>yourApp</servlet-name>
  <url-pattern>/fedletapplication</url-pattern>
</servlet-mapping>
```

Follow these steps for a very simple demonstration of how to customize the Fedlet.

1. Backup fedletSampleApp.jsp.

```
$ cd /path/to/tomcat/webapps/fedlet/
$ cp fedletSampleApp.jsp fedletSampleApp.jsp.orig
```

2. Edit fedletSampleApp.jsp to reduce it to a single redirection to myapp.jsp. An implementation of the <html> element of the file follows below.

```
<html>
<head>
  <title>Fedlet Sample Application</title>
  <meta http-equiv="Content-Type" content="text/html; charset=iso-8859-1" />
</head>

<body>
<%
  // BEGIN : following code is a must for Fedlet (SP) side application
  Map map;
  try {
    // invoke the Fedlet processing logic. this will do all the
    // necessary processing conforming to SAMLv2 specifications,
    // such as XML signature validation, Audience and Recipient
    // validation etc.
    map = SPACUtils.processResponseForFedlet(request, response);
    response.sendRedirect("myapp.jsp");
  } catch (SAML2Exception sme) {
    SAMLUtils.sendError(request, response,
      response.SC_INTERNAL_SERVER_ERROR, "failedToProcessSSOResponse",
      sme.getMessage());
    return;
  } catch (IOException ioe) {
    SAMLUtils.sendError(request, response,
      response.SC_INTERNAL_SERVER_ERROR, "failedToProcessSSOResponse",
      ioe.getMessage());
    return;
  } catch (SessionException se) {
```

```
SAMLUtils.sendError(request, response,
    response.SC_INTERNAL_SERVER_ERROR, "failedToProcessSSOResponse",
    se.getMessage());
return;
} catch (ServletException se) {
    SAMLUtils.sendError(request, response,
        response.SC_BAD_REQUEST, "failedToProcessSSOResponse",
        se.getMessage());
    return;
}
// END : code is a must for Fedlet (SP) side application
%>
</body>
</html>
```

3. Add a myapp.jsp page to the Fedlet, such as the following.

```
<html>
<head>
<title>My Application</title>
<meta http-equiv="Content-Type" content="text/html" />
</head>

<body>
<h1>My Application</h1>
<p>After you change the <code>fedletSampleApp.jsp</code>,
    all it does is redirect to this home page after
    successful login.</p>
<p>See the fedlet README file and example JSPs for hints
    on how to retrieve attributes from OpenAM, or to send
    XACML queries for policy decisions.</p>
</body>
</html>
```

4. Browse to the Fedlet URL, such as <http://www.example.com:8080/fedlet/>, and try one of the login methods.

After login you are redirected to myapp.jsp.

8.1. Signing & Encryption

By default when you create the Java Fedlet, signing and encryption are not configured. You can however set up OpenAM and the fedlet to sign and to verify XML signatures and to encrypt and to decrypt data such as SAML assertions.

Enable signing and encryption for the Java Fedlet involves the following high level stages.

- Before you create the Fedlet, configure the IDP to sign and encrypt data. See Federation > Entity Providers > *IDP Name* > Signing and Encryption in the OpenAM console.

For evaluation, you can use the test certificate delivered with OpenAM.

- Initially deploy and configure the Fedlet, but do not use the Fedlet until you finish.
- On the Fedlet side set up a JKS keystore used for signing and encryption. For evaluation, you can use copy the keystore.jks file delivered with OpenAM. You can find the file under the configuration directory for OpenAM, such as \$HOME/openam/openam/ for a server instance with base URI openam. The built-in keystore includes the test certificate.

You must also set up .storepass and .keypass files using the fedletEncode.jsp page, such as <http://www.example.com:8080/fedlet/fedletEncode.jsp>, to encode passwords on the Fedlet side. The passwords for the test key store and private key are both changeit.

- Configure the Fedlet to perform signing and encryption by ensuring the Fedlet has access to the key store, and by updating the SP metadata for the Fedlet.
- Import the updated SP metadata into the IDP to replace the default Fedlet configuration.
- Restart the Fedlet or container in which the Fedlet runs for the changes you made on the Fedlet side to take effect.

Procedure 8.4. To Configure the Fedlet For Signing & Encryption

The FederationConfig.properties file specifies the paths to the JKS keystore holding the signing or encryption keys for the Fedlet, the keystore password file, and the private key password file.

1. After setting up your keystore and password files as described above, edit the properties file in the configuration directory, such as \$HOME/fedlet/FederationConfig.properties, to point to the keystore and password files.
2. Export the certificate to use for signing and encryption purposes.

```
$ keytool -export -rfc -keystore keystore.jks -alias test
Enter keystore password:

```

3. Edit the standard metadata file for the Fedlet, such as \$HOME/fedlet/sp.xml, to include the certificate in KeyDescriptor elements, that are children of the SPSSODescriptor element.

```
<EntityDescriptor
  xmlns="urn:oasis:names:tc:SAML:2.0:metadata"

5. In OpenAM console delete the original SP entity configuration for the Fedlet, and then import the updated metadata for the new configuration into OpenAM on the IDP side.
6. Restart the Fedlet or the container in which it runs in order for the Fedlet to pick up the changes to the configuration properties and the metadata.

Chapter 9. Using Fedlets in .NET Applications

This chapter explains how to use the Fedlet in your .NET application. You must configure the OpenAM .NET Fedlet to work with the identity provider. Before creating the Fedlet, therefore, set up a Hosted Identity Provider in OpenAM.

Procedure 9.1. To Install the .NET Fedlet as a Demo Application

Before you start, create the hosted identity provider, and the Circle of Trust to which you plan to add the Fedlet. You can perform these steps using the Create Hosted Identity Provider wizard on the Common Tasks page of the OpenAM console. The .NET Fedlet demo requires a signing key for the Identity Provider. For evaluation, use the test certificate installed with OpenAM.

Follow these steps to configure and install the .NET Fedlet demo application.

1. Download the .NET Fedlet (Fedlet-aspnet.zip) from the OpenAM download page. Unpack the contents of the .zip file into a working directory.

bin\

This folder contains the Fedlet.dll library, that you copy to your application's bin\ folder.

conf\

This folder contains the templates you edit to prepare your Fedlet configuration, including the identity provider and Fedlet (SP) metadata for federation. The completed configuration files belong in your application's App_Data\ folder.

readme.txt

This file describes how to set up and configure .NET Fedlets.

SampleApp\

This folder contains the demo application.

2. Edit the template files in the SampleApp\App_Data\ folder based on where you deploy the Fedlet demo application, and on how your identity provider is configured.
 - Edit fedlet.cot to set cot-name to the name of the Circle of Trust, and to set sun-fm-trusted-providers to include the entity ID of the identity provider, and the entity ID of the Fedlet service provider.
 - Edit sp.xml and sp-extended.xml to configure the entity IDs, URLs, and Circle of Trust names to correspond to your sample application.

-
3. Export the identity provider metadata from OpenAM, and copy the resulting idp.xml and idp-extended.xml metadata to the Fedlet SampleApp \App_Data\ folder.

```
$ ssoadm
create-metadata-templ
--entityid "http://idp.example.com:8080/openam"
--adminid amadmin
--password-file /tmp/pwd.txt
--identityprovider /idp
--meta-data-file idp.xml
--extended-data-file idp-extended.xml
--idpscertain alias test

Hosted entity configuration was written to idp-extended.xml.
Hosted entity descriptor was written to idp.xml.
```

4. Register the Fedlet with OpenAM as a remote service provider using the sp.xml and sp-extended.xml metadata.

```
$ ssoadm
import-entity
--adminid amadmin
--password-file /tmp/pwd.txt
--cot fedlet-cot
--meta-data-file sp.xml
--extended-data-file sp-extended.xml

Import file, sp.xml.
Import file, sp-extended.xml.
```

5. Deploy the demo application in Internet Information Server.

Note

IIS must be installed with ASP.NET and additional application support necessary for web applications beyond static web sites. The additional support is not necessarily installed by default when you activate IIS as a Windows feature.

6. Try the demo application links to run Fedlet initiated single sign on using HTTP POST binding and HTTP Artifact binding.

If you are using the embedded directory as a user store, you can authenticate to OpenAM using the demo user whose password is changeit.

Chapter 10. Using Secure Attribute Exchange

Important

This samples mentioned in this chapter are not available in the current release.

Most deployments can rely on OpenAM to handle authentication and provide identity assertions. Not only does OpenAM support a wide variety of authentication scenarios out of the box, but OpenAM also makes it possible to add custom authentication modules. Furthermore OpenIG lets you integrate legacy systems into your access management deployment.

In a deployment where you need OpenAM to act as a SAML 2.0 gateway to a legacy application that serves as an identity provider, you can use OpenAM Secure Attribute Exchange (SAE). On the identity provider side, SAE lets OpenAM retrieve the information needed to create assertions from an external authentication service, bypassing OpenAM authentication and trusting the external service as the authoritative source of authentication. On the service provider side, SAE lets OpenAM securely provide attributes to an application that makes its own policy decision based on the attributes rather than rely on OpenAM for the policy decision.

When you use SAE on the identity provider side, an external application acts as the authoritative source of authentication. After a user authenticates successfully, the application lets OpenAM know to create a session by sending a secure HTTP GET or POST to OpenAM that asserts the identity of the user. OpenAM processes the assertion to create a session for the user. If the user is already authenticated and comes back to access the application, the application sends a secure HTTP POST to OpenAM to assert both the user's identity and also any necessary attributes related to the user. OpenAM processes the assertion to create the session for the user and populate the attributes in the user's session. When the user logs out, the external authentication application can initiate single logout from the identity provider OpenAM server by sending the `sun.cmd=logout` attribute to OpenAM using SAE.

On the service provider side OpenAM communicates using SAML 2.0 with OpenAM on the identity provider side. OpenAM can use SAE to transmit attributes to an application through a secure HTTP POST.

SAE relies either on shared keys and symmetric encryption, or on public and private keys and asymmetric encryption to protect attributes communicated between OpenAM and external applications.

OpenAM ships with sample JSPs that demonstrate secure attribute exchange. In order to try the sample, you must set up an OpenAM circle of trust to include an identity provider and a service provider, install the SDK sample web application on each provider and then configure the providers appropriately as described in this chapter to secure communications with the sample SAE applications on both the identity provider and service provider sides.

10.1. Installing the Samples

Set up an OpenAM server as an identity provider, and another as a service provider, connecting the two in a circle of trust called `samplesaml2cot`. Configure both the hosted providers and also the remote providers as described in *Setting Up SAML 2.0 SSO*. This chapter assumes you set up the hosted identity provider at `http://idp.example.com:8080/openam` and the hosted service provider at `http://sp.example.com:8080/openam`. Use Common Tasks > Test Federation Connectivity in OpenAM console to make sure Federation is working before you add secure attribute exchange applications that rely on functioning SAML 2.0 communications between the providers.

Set up the sample web application as described in *Installing OpenAM Client SDK Samples*, both on the identity provider side and also on the service provider side. The SAE samples are found under `/saml2/sae` where you installed the samples. `saeIDPApp.jsp` is the identity provider side external application. `saeSPApp.jsp` is the service provider side external application.

10.2. Preparing to Secure SAE Communications

In order for SAE to be secure, you must both set up a trust relationship between the application on the identity provider side and the OpenAM server acting as identity provider, and also set up a trust relationship between the application on the service provider side and the OpenAM server acting as the service provider. These trust relationships can be based on a shared secret and symmetric encryption, or on public and private key pairs and asymmetric encryption. The trust relationships on either side are independent. In other words you can for example use a shared secret on the identity provider side and certificates on the service provider side if you chose.

When using symmetric encryption, you must define a shared secret string used both for the application and the provider. The sample uses `secret12` as

the shared secret. To simplify configuration, the sample uses the same shared secret, and thus symmetric encryption, for both trust relationships.

When using symmetric encryption, you must also use the encoded version of your shared secret. To get the encoded version of a shared secret string, use the `encode.jsp` page on the provider, as in `http://idp.example.com:8080/openam/encode.jsp` and `http://sp.example.com:8080/openam/encode.jsp`. An encoded version of `secret12` looks something like `AQICEcFhDWmb6sVmMuCJuVh43306HVacDte9`.

When using asymmetric encryption, you must obtain a public-private key pair for the application, and store the keys in a key store on the application side. Also store the public key from OpenAM which is acting as the provider in the application's key store. Make note of the certificate aliases for your application's private key, and for OpenAM's public key. Also note the path to the key store for your application, the key store password, and the private key password.

10.3. Securing the Identity Provider Side

This configuration uses the default sample settings with a shared secret of `secret12`, without encryption of the attributes.

1. Login as `amadmin` to the OpenAM server console where you set up the hosted identity provider (IDP).
2. As the sample includes a branch attribute not found in user profiles by default, under `Access Control > Realm Name > Authentication > All Core Settings...`, set `User Profile` to `Ignored`, and then `Save your work`.
3. Under `Federation > Entity Providers`, click the name for the Hosted IDP in order to access the IDP configuration.
 - Under `Assertion Processing > Attribute Mapper`, add both `mail=mail` and `branch=branch` to the attribute map, and then `Save your work`.
 - Under `Advanced > SAE Configuration`, make sure the IDP URL reflects an endpoint on the IDP such as `http://idp.example.com:8080/openam/idpsaehandler/metaAlias/idp`, and then `Save your work`.
 - Also under `Advanced > SAE Configuration > Application Security Configuration`, add the URL value for the kind of encryption you are using, and then `Save your work`.

When using the defaults, the value is something like `url=http://idp.example.com:8080/samples/saml2/sae/saeIDPApp.jsp?type=symmetric|secret=encoded-secret`, where the OpenAM SDK sample web application is deployed on the IDP side

with context root `/samples` and the *encoded-secret* is something like `AQICEcFhDWmb6sVmMuCJuVh43306HVacDte9`.

If you use a different mechanism to secure the communications between the SAE application and the provider, read the online help in the console to see how to construct your URL value.

4. Under Federation > Entity Providers, click the name for the Remote SP in order to access the SP configuration on the IDP side.
 - Under Assertion Processing > Attribute Mapper, add both `mail=mail` and `branch=branch` to the attribute map, and then Save your work.
 - Under Advanced > SAE Configuration, make sure the SP URL reflects an endpoint on the SP such as `http://sp.example.com:8080/openam/spsaehandler/metaAlias/sp`, and then Save your work.
 - Also under Advanced > SAE Configuration, add the URL to the sample SAE application as the SP Logout URL such as `http://sp.example.com:8080/samples/saml2/sae/saeSPApp.jsp`, and then Save your work.

10.4. Securing the Service Provider Side

This configuration uses the default sample setting of symmetric encryption, with a shared secret of `secret12`.

Login as `amadmin` to the OpenAM server console where you set up the hosted service provider (SP).

1. As the sample includes a branch attribute not found in user profiles by default, under Access Control > *Realm Name* > Authentication > All Core Settings..., set User Profile to Ignored, and then Save your work.
2. Under Federation > Entity Providers, click the name for the Hosted SP in order to access the SP configuration.
 - Under Assertion Processing > Attribute Mapper, add both `mail=mail` and `branch=branch` to the attribute map, and then Save your work.
 - Also under Assertion Processing > Attribute Mapper > Auto Federation, select Enabled, set the Attribute to `mail`, and then Save your work.
 - Under Advanced > SAE Configuration, make sure the SP URL reflects an endpoint on the SP such as `http://sp.example.com:8080/openam/spsaehandler/metaAlias/sp`, and then Save your work.
 - Furthermore, under Advanced > SAE Configuration, add the URL to the sample SAE application as the SP Logout URL such as `http://`

`sp.example.com:8080/samples/saml2/sae/saeSPApp.jsp`, and then Save your work.

- Also under Advanced > SAE Configuration > Application Security Configuration, add the URL value for the kind of encryption you are using, and then Save your work.

When using the defaults, the value is something like `url=http://sp.example.com:8080/samples/saml2/sae/saeSPApp.jsp|type=symmetric|secret=encoded-secret`, where the OpenAM SDK sample web application is deployed on the IDP side with context root `/samples` and the `encoded-secret` is something like `AQICKX24RbZboAVgr2FG1kWoqRv1zM2a6KEH`.

If you use a different mechanism to secure the communications between the SAE application and the provider, read the online help in the console to see how to construct your URL value.

10.5. Trying It Out

After completing the setup described above, navigate to the IDP side SAE application, for example at `http://idp.example.com:8080/samples/saml2/sae/saeIDPApp.jsp`.

Make sure you set at least the "SP App URL" and "SAE URL on IDP end" to fit your configuration. For example if you used the settings above then use the following values.

SP App URL

`http://sp.example.com:8080/samples/saml2/sae/saeSPApp.jsp`

SAE URL on IDP end

`http://idp.example.com:8080/openam/idpsaehandler/metaAlias/idp`

Check the settings, and then click Generate URL to open the Secure Attributes Exchange IDP APP SAMPLE page.

Click the `ssourl` link in the page to start the exchange.

The resulting web page shows the attributes exchanged, including the mail and branch values used. The text of that page is something like the following.

SAE SP APP SAMPLE

Secure Attrs :

| | |
|-----------------|------------------------------------|
| mail | testuser@foo.com |
| sun.idpentityid | http://idp.example.com:8080/openam |
| sun.spentityid | http://sp.example.com:8080/openam |
| branch | mainbranch |
| sun.authlevel | 0 |

Chapter 11. Using the OpenAM C API

Important

This samples mentioned in this chapter are not available in the current release.

This chapter introduces OpenAM C SDK. OpenAM C SDK is delivered for selected platforms in `libraries/native/agent-csdk/agent-csdk.zip` where you unpacked the full version of OpenAM. To prepare to install OpenAM C SDK, first unzip `agent-csdk.zip`.

```
$ unzip ~/Downloads/opensso/libraries/native/agent-csdk/agent-csdk.zip
Archive:  ~/Downloads/opensso/libraries/native/agent-csdk/agent-csdk.zip
  inflating: README
  inflating: agent-csdk-linux-32.tar.gz
  inflating: agent-csdk-linux-64.tar.gz
  inflating: agent-csdk-solaris-sparc-32.tar.gz
  inflating: agent-csdk-solaris-sparc-64.tar.gz
  inflating: agent-csdk-solaris-x86-32.tar.gz
  inflating: agent-csdk-solaris-x86-64.tar.gz
  extracting: agent-csdk-windows-32.zip
  extracting: agent-csdk-windows-64.zip
```

Unpack the archive for your platform.

```
$ mkdir -p /path/to/openam-client ; cd /path/to/openam-client
$ tar xzvf /path/to/agent-csdk-linux-32.tar.gz
```

As a result, you have several directories that include the SDK and also sample client applications.

- bin/
 - The **crypt_util** or **cryptit.exe** command for encrypting passwords
- config/
 - Configuration data for the SDK
- include/
 - Header files for the SDK
- lib/
 - SDK and other required libraries
- samples/
 - Sample code

Procedure 11.1. To Build OpenAM C SDK Samples

1. Review the `samples/README.TXT` file to complete any specific instructions required for your platform.

```
$ uname -s
Linux
$ cd ../lib
$ ln -s libamsdk.so.3 libamsdk.so
$ ln -s libxml2.so.2 libxml2.so
$ cd ../samples
```

2. Build the samples in the appropriate way for your platform.

```
$ LD_LIBRARY_PATH=../lib make
```

On recent systems, you might need to install compatibility libraries for the build to complete successfully. You might make the following change on Linux, for example.

```
$ diff Makefile Makefile.orig
l15c115
< LDFLAGS = -L$(AM_LIB_DIR) $(LIBS) /usr/lib/libstdc++.so.5
---
> LDFLAGS = -L$(AM_LIB_DIR) $(LIBS)
```

3. Set up `OpenSSOAgentBootstrap.properties` and `OpenSSOAgentConfiguration.properties` as appropriate for your environment.

Base your work on the template files in the `config/` directory. You can find the Password Encryption Key in the OpenAM console under Configuration > Servers and Sites > *Server Name* > Security.

4. Try one of the samples you built to test your build.

```
$ LD_LIBRARY_PATH=../lib
./am_auth_test
-f ../config/OpenSSOAgentBootstrap.properties
-u demo
-p changeit
-o /
Login 1 Succeeded!
SSOToken = AQIC5wM2LY4SfcxZfk4EzC9Y46P9cXG9ogwf2ixnY0eZ0K0.*AAJTSQACMDE.*
Organization = /
Module Instance Name [0] = SAE
Module Instance Name [1] = LDAP
Module Instance Name [2] = WSSAuthModule
Module Instance Name [3] = Federation
Module Instance Name [4] = HOTP
Module Instance Name [5] = DataStore
Logout 1 Succeeded!
```

Chapter 12. Extending OpenAM

OpenAM services solve a wide range of access and federation management problems out of the box. Yet, OpenAM also exposes APIs and SPIs that enable you extend OpenAM services when built-in functionality does not fit your deployment.

This part of the guide covers OpenAM mechanisms for plugging in additional functionality not available out of the box.

Chapter 13. Customizing Profile Attributes

You can extend user profiles by adding custom attributes. This chapter demonstrates how to add a custom attribute to a user profile when storing user profiles in the embedded LDAP directory.

Adding a custom attribute involves both updating the `iPlanetAMUserService`, and also updating the identity repository schema to hold the new attribute. Furthermore, to allow users to update the attribute in their own profiles, you must also update the OpenAM policy configuration stored in the configuration directory.

Procedure 13.1. To Update the AMUser Service For the New Attribute

Follow the steps below to create a custom attribute in OpenAM.

1. Create a backup copy of the configuration file for the `iPlanetAMUserService`.

```
$ cd $HOME
$ cp openam/config/xml/amUser.xml openam/config/xml/amUser.xml.orig
```

2. Edit the file to add your attribute as one of the list of `<User>` attributes.

```
<AttributeSchema name="customAttribute"
  type="single"
  syntax="string"
  any="display"
  i18nKey="Custom Attribute">
</AttributeSchema>
```

Here, the name refers to the attribute type name used in LDAP. The `i18nKey` holds either the reference, or in this case the content, of the text that appears in the user interface.

3. Delete `iPlanetAMUserService`, and then create it from your updated configuration file.

```
$ cd /path/to/tools/openam/bin/
$ ssoadm
delete-svc
--adminid amadmin
--password-file /tmp/pwd.txt
--servicename iPlanetAMUserService

Service was deleted.
$ ssoadm
create-svc
--adminid amadmin
--password-file /tmp/pwd.txt
```

```
--xmlfile $HOME/openam/config/xml/amUser.xml  
Service was added.
```

Procedure 13.2. To Update the Identity Repository For the New Attribute

Follow the steps below to update the identity repository LDAP schema for the custom attribute, and then update OpenAM to use the custom attribute and object class.

Tip

If you are using OpenDJ as the identity repository, you can update the schema through OpenDJ Control Panel > Schema > Manage Schema, as described in the OpenDJ documentation.

1. Prepare the attribute type object class definitions in LDIF format.

```
$ cat custom-attr.ldif  
dn: cn=schema  
changetype: modify  
add: attributeTypes  
attributeTypes: ( temp-custom-attr-oid NAME 'customAttribute' EQUALITY case  
IgnoreMatch ORDERING caseIgnoreOrderingMatch SUBSTR caseIgnoreSubstrings  
Match SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 USAGE userApplications )  
-  
add: objectClasses  
objectClasses: ( temp-custom-oc-oid NAME 'customObjectclass' SUP top AUX  
ILIARY MAY customAttribute )
```

2. Add the schema definitions to the directory.

```
$ /path/to/OpenDJ/bin/ldapmodify  
--port 1389  
--hostname openam.example.com  
--bindDN "cn=Directory Manager"  
--bindPassword password  
--filename custom-attr.ldif  
Processing MODIFY request for cn=schema  
MODIFY operation successful for DN cn=schema
```

3. In OpenAM console, browse to Access Control > *Realm Name* > Data Stores > *Data Store Name*.
4. Add the object class, here `customObjectclass`, to the LDAP User Object Class list.
5. Add the attribute type, here `customAttribute`, to the LDAP User Attributes list.
6. Save your work.

Procedure 13.3. To Allow Users To Update the New Attribute

Follow these steps to make the new attribute editable by users. The steps imply use of the embedded configuration directory. If you use a different directory server to store the configuration, then adapt them for your tools.

1. Login to the control panel for the embedded configuration directory.

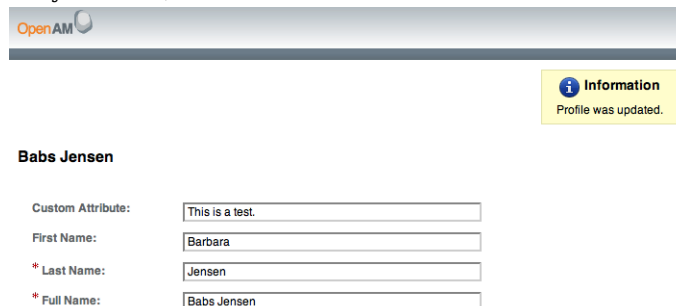

```
$ ./openam/opens/bin/control-panel &
```

Connect using bind DN `cn=Directory Manager` and the the password for `amadmin`.

2. Select Manage Entries to open the LDAP browser.
3. Search with LDAP Filter: set to `ou=SelfWriteAttributes`, and then expand the tree views to see the two entries found.
4. In the entry under `iPlanetAMPolicyService`, edit the `sunKeyValue` attribute to add your custom attribute to the list of self-writable attributes, as in `<Value>customAttribute</Value>`.
5. In the entry under `sunEntitlementIndexes`, edit the `sunKeyValue` attribute to add your custom attribute to the list of self-writable attributes, as in replacing the last `\n` in the list with `,\n \"customAttribute\"\\n`.
6. Restart OpenAM or the web container where it runs.

```
$ /etc/init.d/tomcat stop  
$ /etc/init.d/tomcat start
```

7. Login to OpenAM console as a user to check that a user can save a value for your new, custom attribute.

OpenAM

Chapter 14. Customizing OAuth 2.0 Scope Handling

RFC 6749, *The OAuth 2.0 Authorization Framework*, describes access token scopes as a set of case-sensitive strings defined by the authorization server. Clients can request scopes, and resource owners can authorize them.

The default scopes implementation in OpenAM treats scopes as profile attributes for the resource owner. When a resource server or other entity uses the access token to get token information from OpenAM, OpenAM populates the scopes with profile attribute values. For example, if one of the scopes is mail, OpenAM sets mail to the resource owner's email address in the token information returned.

You can change this behavior by writing your own scopes plugin. This chapter shows how to write a custom OAuth 2.0 scopes plugin for use in an OAuth 2.0 provider (authorization server) configuration.

14.1. Designing an OAuth 2.0 Scopes Plugin

A scopes plugin implements the `org.forgerock.openam.oauth2.provider.Scope` interface. The `Scope` interface has four methods that your plugin overrides.

```
public Set<String> scopeToPresentOnAuthorizationPage(  
    Set<String> requestedScope,  
    Set<String> availableScopes,  
    Set<String> defaultScopes);  
  
public Set<String> scopeRequestedForAccessToken(  
    Set<String> requestedScope,  
    Set<String> availableScopes,  
    Set<String> defaultScopes);  
  
public Set<String> scopeRequestedForRefreshToken(  
    Set<String> requestedScope,  
    Set<String> availableScopes,  
    Set<String> allScopes,  
    Set<String> defaultScopes);  
  
public Map<String, Object> evaluateScope(AccessToken token);
```

The first three methods return the scopes to display when the resource owner makes the authorization decision, or when an access token or refresh token is granted, respectively. The fourth method, `evaluateScope` can be used to set values for scopes returned when token information is requested.

The following example plugin sets whether read and write permissions were granted.

```
package org.forgerock.openam.examples;
```

```
import java.util.HashMap;
import java.util.HashSet;
import java.util.Map;
import java.util.Set;

import org.forgerock.openam.oauth2.model.AccessToken;
import org.forgerock.openam.oauth2.provider.Scope;

/**
 * Custom scope providers implement the
 * {@link org.forgerock.openam.oauth2.provider.Scope} interface.
 *
 * This custom scope implementation follows the OpenAM default scope
 * implementation for all methods except {@link #evaluateScope}.
 *
 * The {@code evaluateScope} method is called when a client accesses
 * the {@code /tokeninfo} endpoint to retrieve token information.
 *
 * In this example, the method populates scope values returned in the
 * JSON with the token information.
 */
public class CustomScope implements Scope {

    @Override
    public Set<String> scopeToPresentOnAuthorizationPage(
        Set<String> requestedScope,
        Set<String> availableScopes,
        Set<String> defaultScopes) {

        if (requestedScope == null) {
            return defaultScopes;
        }

        Set<String> scopes = new HashSet<String>(availableScopes);
        scopes.retainAll(requestedScope);
        return scopes;
    }

    @Override
    public Set<String> scopeRequestedForAccessToken(
        Set<String> requestedScope,
        Set<String> availableScopes,
        Set<String> defaultScopes) {

        if (requestedScope == null){
            return defaultScopes;
        }

        Set<String> scopes = new HashSet<String>(availableScopes);
        scopes.retainAll(requestedScope);
        return scopes;
    }

    @Override
    public Set<String> scopeRequestedForRefreshToken(
        Set<String> requestedScope,
        Set<String> availableScopes,
        Set<String> allScopes,
        Set<String> defaultScopes) {

        if (requestedScope == null){
```

```
        return defaultScopes;
    }

    Set<String> scopes = new HashSet<String>(availableScopes);
    scopes.retainAll(requestedScope);
    return scopes;
}

@Override
public Map<String, Object> evaluateScope(AccessToken token) {
    Set<String> scopes = token.getScope();

    Map<String, Object> map = new HashMap<String, Object>();
    String[] permissions = {"read", "write"};

    for (String scope : permissions) {
        if (scopes.contains(scope)) {
            map.put(scope, true);
        } else {
            map.put(scope, false);
        }
    }

    return map;
}
}
```

14.2. Building an OAuth 2.0 Scopes Plugin

As the plugin imports at least `org.forgerock.openam.oauth2.model.AccessToken` and `org.forgerock.openam.oauth2.provider.Scope`, add `openam-oauth2-common-10.1.0-Xpress.jar` to the classpath.

After compiling, put it in a .jar file that you can deploy with OpenAM.

```
$ mkdir classes
$ javac -d classes
  -cp /path/to/.../openam/WEB-INF/lib/openam-oauth2-common-10.1.0-Xpress.jar
  CustomScope.java
$ cd classes/
$ jar cf ../CustomScope.jar
```

14.3. Configuring OpenAM to Use the Plugin

After building your plugin jar file, add the file under `WEB-INF/lib/` where you deployed OpenAM.

Restart OpenAM.

In OpenAM console, you can either configure a specific OAuth 2.0 provider to use your plugin, or configure your plugin as the default for new OAuth 2.0 providers. To configure a specific OAuth 2.0 provider to use your plugin, add the class name of your scopes plugin under Access Control > *Realm Name* >

Services > *OAuth2 Provider Name* > Scope Implementation Class. To configure your plugin as the default for new providers, add the class name of your scopes plugin under Configuration > Global > OAuth2 Provider > Scope Implementation Class.

14.4. Trying the Example Plugin

If you build the example plugin shown above in Section 14.1, “Designing an OAuth 2.0 Scopes Plugin”, and then create an OAuth 2.0 client that takes scopes read and write, you can configure OpenAM to use the plugin, and then try it as shown in the following example.

```
$ curl
-d "grant_type=client_credentials&username=demo&password=changeit
&client_id=myClientID&client_secret=password&scope=read"
http://oauth2.example.com:8080/openam/oauth2/access_token
{
  "expires_in": 599,
  "token_type": "Bearer",
  "access_token": "84122d5e-0462-4d81-93c3-7bc58bd416b3"
}
$ curl http://oauth2.example.com:8080/openam/oauth2/tokeninfo
?access_token=84122d5e-0462-4d81-93c3-7bc58bd416b3
{
  "write": false,
  "read": true,
  "token_type": "Bearer",
  "expires_in": 539,
  "access_token": "84122d5e-0462-4d81-93c3-7bc58bd416b3"
}
```

Chapter 15. Customizing Authentication Modules

This chapter shows how to customize authentication with a sample custom authentication module. For deployments with particular requirements not met by existing OpenAM authentication modules, determine whether you can adapt one of the built-in or extension modules for your needs. If not, build the functionality into a custom authentication module.

15.1. About the Sample Authentication Module

The sample authentication module prompts for a user name and password to authenticate the user, and handles error conditions. The sample shows how you integrate an authentication module into OpenAM such that you can configure the module through OpenAM console, and also localize the user interface.

The name for the sample authentication module is `SampleAuth`. Notice how this name is used to form module component names according to OpenAM conventions.

An OpenAM authentication module is comprised of five components.

- The authentication logic, which is a class that extends the `com.sun.identity.authentication.spi.AMLoginModule` class. In this case, `SampleAuth.java`.
- The principal, which is a class that implements the `java.security.Principal` interface. In this case, `SampleAuthPrincipal.java`.
- The callbacks XML file, which describes the states of authentication logic and the user input needed for each state. In this case there is one file, `SampleAuth.xml`.
- The service configuration XML file, which defines how the authentication module is configured in OpenAM. In this case, `amAuthSampleAuth.xml`.
- The properties files for the module, which map localized strings to identifiers used elsewhere in the module. In this case, `amAuthSampleAuth.properties`.

15.2. The Sample Auth Callbacks

OpenAM callbacks XML files prompt the user for identity information needed to process the authentication. The document type for a callback XML file is described in `war-file-name/WEB-INF/Auth_Module_Properties.dtd`.

Tip

Callback files for built-in modules are under *war-file-name/config/auth/default/*; extension modules are stored in the OpenAM source tree.

Example 15.1. Simplified Callbacks File

This example shows a simplified sample auth callbacks XML file that does no error handling. The file specifies only one state (*order="1"*), and prompts the user for two pieces of information: user name and password. All strings for the user interface are hard coded into the file.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE ModuleProperties PUBLIC
    "-//iPlanet//Authentication Module Properties XML Interface 1.0 DTD//EN"
    "jar://com/sun/identity/authentication/Auth_Module_Properties.dtd">

<ModuleProperties moduleName="SampleAuth" version="1.0" >
    <Callbacks length="2" order="1" timeout="600" header="Please Login" >
        <NameCallback isRequired="true">
            <Prompt> User Name: </Prompt>
        </NameCallback>
        <PasswordCallback echoPassword="false" >
            <Prompt> Password: </Prompt>
        </PasswordCallback>
    </Callbacks>
</ModuleProperties>
```

Example 15.2. Full Callbacks File

This example shows a full callbacks file with dynamic text and error handling. Use this as your SimpleAuth.xml file.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE ModuleProperties PUBLIC
  "-//iPlanet//Authentication Module Properties XML Interface 1.0 DTD//EN"
  "jar://com/sun/identity/authentication/Auth_Module_Properties.dtd">

<ModuleProperties moduleName="SampleAuth" version="1.0" >
  <Callbacks length="0" order="1" timeout="600" header="#NOT SHOWN#" />
  <Callbacks length="2" order="2" timeout="600" header="#TO BE SUBSTITUTED#">
    <NameCallback isRequired="true">
      <Prompt>#USERNAME#</Prompt>
    </NameCallback>
    <PasswordCallback echoPassword="false" >
      <Prompt>#PASSWORD#</Prompt>
    </PasswordCallback>
  </Callbacks>
  <Callbacks length="1" order="3" timeout="600" header="#TO BE SUBSTITUTED#"
    error="true" >
    <NameCallback>
      <Prompt>#THE DUMMY WILL NEVER BE SHOWN#</Prompt>
    </NameCallback>
  </Callbacks>
</ModuleProperties>
```

This file specifies three states.

1. The initial state (order="1") is used dynamically to replace the dummy strings shown between hashes (for example, #USERNAME#) by the substituteUIStrings() method in SampleAuth.java.
2. The next state (order="2") handles prompting the user for authentication information.
3. The last state (order="3") has the attribute error="true". If the authentication module state machine reaches this order then the authentication has failed. The NameCallback is not used and not displayed to user. OpenAM requires that the callbacks array have at least one element. Otherwise OpenAM does not permit header substitution.

15.3. The Sample Authentication Logic

An OpenAM authentication module must extend the com.sun.identity.authentication.spi.AMLoginModule abstract class, and must implement the methods shown below.

See the *OpenAM Java SDK API Specification* for reference.

```
// OpenAM calls the init() method once when the module is created.
public void init(Subject subject, Map sharedState, Map options)
```

The Sample Authentication Logic

```
// OpenAM calls the process() method when the user submits authentication
// information. The process() method determines what happens next:
// success, failure, or the next state specified by the order
// attribute in the callbacks XML file.
public int process(Callback[] callbacks, int state) throws LoginException

// OpenAM expects the getPrincipal() method to return an implementation of
// the java.security.Principal interface.
public Principal getPrincipal()
```

OpenAM does not reuse authentication module instances. This means that you can store information specific to the authentication process in the instance.

The implementation, `SimpleAuth.java`, is shown below.

```

 *
 * @return a hash code for this <code> SampleAuthPrincipal </code>.
 */
@Override
public int hashCode()
{
    return name.hashCode();
}
}
```

15.5. The Sample Auth Service Configuration

OpenAM requires that all authentication modules be configured by means of an OpenAM service. At minimum, the service must include an authentication level attribute. Your module can access these configuration attributes in the options parameter passed to the `init()` method.

Some observations about the service configuration file follow in the list below.

- The document type for a service configuration file is described in *war-file-name/WEB-INF/sms.dtd*.
- The service name is taken from the module name: `iPlanetAMAuthmodule-nameService`. In this case, the service name is `iPlanetAMAuthSampleAuthService`.
- The service must have a localized description, retrieved from a properties file.

The Sample Auth Service Configuration

- The `i18nFileName` attribute in the service configuration holds the default (non-localized) base name of the Java properties file. The `i18nKey` attributes indicate properties keys to string values in the Java properties file.
- The authentication level attribute name is taken from the module name: `iplanet-am-auth-module-name-auth-level`, where the *module-name* is all lower case. Here, the authentication level attribute is named `iplanet-am-auth-sampleauth-auth-level`.
- The Sample Auth service configuration includes an example `sampleauth-service-specific-attribute`, which can be configured through OpenAM console.

The service configuration file, `amAuthSampleAuth.xml`, is shown below.

```
<?xml version="1.0" encoding="UTF-8"?>
<!--

    type="single" syntax="string" validator="no" i18nKey="a501">
    <DefaultValues>
      <Value></Value>
    </DefaultValues>
  </AttributeSchema>

</SubSchema>
</Organization>
</Schema>
</Service>
</ServicesConfiguration>
```

15.6. The Sample Auth Properties

OpenAM uses a Java properties file per locale to retrieve the appropriate, localized strings for the authentication module. The default properties file, `amAuthSampleAuth.properties`, is shown below.

```
sampleauth-service-description=Sample Authentication Module
a500=Authentication Level
a501=Service Specific Attribute

sampleauth-ui-login-header=Login
sampleauth-ui-username-prompt=User Name:
sampleauth-ui-password-prompt=Password:

sampleauth-error-1=Error 1 occurred during the authentication
sampleauth-error-2=Error 2 occurred during the authentication
```

15.7. Building & Installing the Sample Auth Module

Once you have the files for the sample authentication module, build the module, and then install the module into OpenAM.

15.7.1. Building the Module

The sample authentication module code relies on three .jar files, two of which are deployed with OpenAM, and the third which is provided by your web application container.

amserver.jar

When you deploy OpenAM, the file is *war-file-name*/WEB-INF/lib/amserver.jar.

opensso-sharedlib.jar

When you deploy OpenAM, the file is *war-file-name*/WEB-INF/lib/opensso-sharedlib.jar.

servlet-api.jar

This jar provides the Java EE Servlet API.

If you use Apache Tomcat as your web application container, the file is /path/to/tomcat/lib/servlet-api.jar.

Put these libraries for example in a lib/ directory, and then put them on your CLASSPATH to compile the custom authentication authentication module classes.

```
$ mkdir classes
$ javac -d classes -cp lib/servlet-api.jar:lib/amserver.jar:
lib/opensso-sharedlib.jar src/com/forgerock/openam/examples/SampleAuth*.java
```

Add the resulting classes to a new sampleauth.jar file.

```
$ cd classes/
$ jar cf ../sampleauth.jar .
```

15.7.2. Installing the Module

Installing the sample authentication module consists of putting the .jar and other files in the right places, registering the module with OpenAM, and then restarting the web application or the web application container.

Copy the sampleauth.jar file to *war-file-name*/WEB-INF/lib/ where OpenAM is deployed.

```
$ cp sampleauth.jar /path/to/tomcat/webapps/openam/WEB-INF/lib/
```

Copy the amAuthSampleAuth.properties file to *war-file-name*/WEB-INF/classes/ where OpenAM is deployed.

```
$ cp amAuthSampleAuth.properties /path/to/tomcat/webapps/openam/WEB-INF/classes/
```

Copy the amAuthSampleAuth.xml service definition file to *war-file-name*/WEB-INF/classes/ where OpenAM is deployed.

```
$ cp amAuthSampleAuth.xml /path/to/tomcat/webapps/openam/WEB-INF/classes/
```

Copy the SimpleAuth.xml callbacks file to *war-file-name*/config/auth/default/ where OpenAM is deployed.

```
$ cp SampleAuth.xml /path/to/tomcat/webapps/openam/config/auth/default/
```

Register the module with OpenAM using the **ssoadm** command.

```
$ ssoadm
create-svc
--adminid amadmin
--password-file /tmp/pwd.txt
--xmlfile amAuthSampleAuth.xml

Service was added.
$ ssoadm
register-auth-module
--adminid amadmin
--password-file /tmp/pwd.txt
--authmodule com.forgerock.openam.examples.SampleAuth

Authentication module was registered.
```

See the **ssoadm** reference a full list of Authentication Service Management subcommands.

Restart OpenAM, or the web applications container where it runs.

```
$ /path/to/tomcat/bin/shutdown.sh
$ /path/to/tomcat/bin/startup.sh
$ tail -1 /path/to/tomcat/logs/catalina.out
INFO: Server startup in 32746 ms
```

15.8. Configuring & Testing the Sample Auth Module

Login to the console as OpenAM administrator, amadmin, and browse to Access Control > *Realm Name* > Authentication > Module Instances. Click New, and then create an instance of your Sample Authentication Module.

After creating the module, click the name in the Module Instances list, and configure as appropriate.

Sample Authentication Module Save Reset Back to Authentication

Realm Attributes

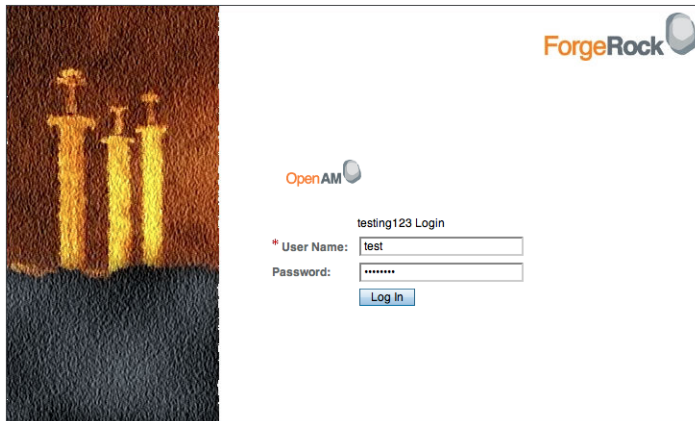

Authentication Level:

Service Specific Attribute:

Add your module to the top of the default authentication chain so that OpenAM considers the module sufficient to login. Also, under All Core Settings... for the realm, set User Profile creation to Dynamic so that successful login results

Now that your module is configured, logout of OpenAM console, to return to the login page.

Configuring & Testing the Sample Auth Module

Copyright © 2010-2011 ForgeRock AS, Philip Pedersen vei 1, 1365 Lysaker, Norway. All rights reserved. Licensed for use under the Common Development and Distribution License (CDDL), see <http://www.forgerock.com/license/CDDLv1.0.html> for details. This software is based on the OpenSSO/OpenAM open source project and the source includes the copyright works of other authors, granted for use under the CDDL. This distribution may include other materials developed by third parties. All Copyrights and Trademarks are property of their owners.

You can try different combinations as seen in `SimpleAuth.java`. Unless you create a test subject with a user profile in OpenAM or set User Profile creation to Dynamic for the login realm, successful login results in an "User has no profile in this organization" error. This is because OpenAM attempts to redirect the authenticated test user to a profile page that does not exist.

Chapter 16. Creating a Post Authentication Plugin

Post authentication plugins (PAP) let you include custom processing at the end of the authentication process, immediately before the subject is authenticated. Common uses of post authentication plugins include setting cookies and session variables. Post authentication plugins are often used in conjunction with policy agents. The post authentication plugin sets custom session properties, and then the policy agent injects the custom properties into the request header to the protected application.

This chapter explains how to create a post authentication plugin.

16.1. Designing Your Post Authentication Plugin

Your post authentication plugin class implements the `AMPPostAuthProcessInterface` interface, and in particular the following three methods.

```
public void onLoginSuccess(
    Map requestParamsMap,
    HttpServletRequest request,
    HttpServletResponse response,
    SSOToken token
) throws AuthenticationException

public void onLoginFailure(
    Map requestParamsMap,
    HttpServletRequest request,
    HttpServletResponse response
) throws AuthenticationException

public void onLogout(
    HttpServletRequest request,
    HttpServletResponse response,
    SSOToken token
) throws AuthenticationException
```

OpenAM calls the `onLoginSuccess()` and `onLoginFailure()` methods immediately before informing the user of login success or failure, respectively. OpenAM calls the `onLogout()` method only when the user actively logs out, not when a user's session times out.

See the *OpenAM Java SDK API Specification* for reference.

These methods can perform whatever processing you require. Yet, know that OpenAM calls your methods synchronously as part of the authentication process. Therefore, if your methods take a long time to complete, you will keep users waiting. Minimize the processing done in your post authentication methods.

16.2. Building Your Sample Post Authentication Plugin

The following example post authentication plugin sets a session property during successful login, writing to its debug log if the operation fails.

```
package com.forgerock.openam.examples;

import java.util.Map;

import com.iplanet.sso.SSOException;
import com.iplanet.sso.SSOToken;

import com.sun.identity.authentication.spi.AMPostAuthProcessInterface;
import com.sun.identity.authentication.spi.AuthenticationException;
import com.sun.identity.shared.debug.Debug;

import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;

public class SamplePAP implements AMPostAuthProcessInterface
{
    private final static String PROP_NAME = "MyProperty";
    private final static String PROP_VALUE = "MyValue";
    private final static String DEBUG_FILE = "SamplePAP";

    protected Debug debug = Debug.getInstance(DEBUG_FILE);

    public void onLoginSuccess(
        Map requestParamsMap,
        HttpServletRequest request,
        HttpServletResponse response,
        SSOToken token
    ) throws AuthenticationException
    {
        try {
            token.setProperty(PROP_NAME, PROP_VALUE);
        } catch (SSOException ssoe) {
            debug.error("Unable to set property");
        }
    }

    public void onLoginFailure(
        Map requestParamsMap,
        HttpServletRequest request,
        HttpServletResponse response
    ) throws AuthenticationException
    {
        ; // Not used
    }

    public void onLogout(
        HttpServletRequest request,
        HttpServletResponse response,
        SSOToken token
    ) throws AuthenticationException
    {
        ; // Not used
    }
}
```

A post authentication plugin code relies on three .jar files, two of which are deployed with OpenAM, and the third which is provided by your web application container.

`amserver.jar`

When you deploy OpenAM, the file is `war-file-name/WEB-INF/lib/amserver.jar`.

`opensso-sharedlib.jar`

When you deploy OpenAM, the file is `war-file-name/WEB-INF/lib/opensso-sharedlib.jar`.

`servlet-api.jar`

This .jar provides the Java EE Servlet API.

If you use Apache Tomcat as your web application container, the file is `/path/to/tomcat/lib/servlet-api.jar`.

Put the sample plugin in `src/com/forgerock/openam/examples/SamplePAP.java`, and compile the class.

```
$ cd src
$ mkdir ../classes
$ javac
  -d ../classes
  -classpath /path/to/tomcat/webapps/openam/WEB-INF/lib/amserver.jar:
    /path/to/tomcat/webapps/openam/WEB-INF/lib/opensso-sharedlib.jar:
    /path/to/tomcat/lib/servlet-api.jar
  com/forgerock/openam/examples/SamplePAP.java
```

Copy the classes to the `WEB-INF/classes` directory where you deployed OpenAM.

```
$ cp -r ../classes/* /path/to/tomcat/webapps/openam/WEB-INF/classes/
```

Restart OpenAM or your web container to ensure the post authentication plugin class is loaded.

```
$ /etc/init.d/tomcat stop
$ /etc/init.d/tomcat start
$ tail -1 /path/to/tomcat/logs/catalina.out
INFO: Server startup in 32070 ms
```

16.3. Configuring Your Post Authentication Plugin

You can configure the post authentication plugin for a realm, for a service (authentication chain), or for a role. Where you configure the plugin depends on the scope to which the plugin should apply. Configuring the plugin at the realm level as shown here, for example, ensures that OpenAM calls your plugin for all authentications to the realm.

In the OpenAM console, browse to Access Control > *Realm Name* > Authentication > All Core Settings... In the Authentication Post Processing Classes list, add the sample plugin class, `com.forgerock.openam.examples.SamplePAP`, and then click Save.

Alternatively, you can configure sample plugin for the realm by using the **ssoadm** command.

```
$ ssoadm
  set-svc-attrs
  --adminid amadmin
  --password-file /tmp/pwd.txt
  --servicename iPlanetAMAuthService
  --realm /realm
  --attributevalues iplanet-am-auth-post-login-process-class=
  com.forgerock.openam.examples.SamplePAP

iPlanetAMAuthService under /realm was modified.
```

16.4. Testing Your Post Authentication Plugin

To test the sample post authentication plugin, login successfully to OpenAM in the scope where the plugin is configured. For example, if you configured your plugin for the realm, `/realm`, specify the realm in the login URL.

```
http://openam.example.com:8080/openam/UI/Login?realm=realm
```

Although as a user you do not notice anywhere in the user interface that OpenAM calls your plugin, a policy agent or custom client code could retrieve the session property your plugin added to the user session.

Chapter 17. Customizing Policy Evaluation

OpenAM policies let you restrict access to resources based both on identity and group membership, and also on a range of conditions including session age, authentication chain or module used, authentication level, realm, session properties, IP address and DNS name, user profile content, resource environment, date, day, time of day, and time zone. Yet, some deployments require further distinctions for policy evaluation. This chapter explains how to customize policy evaluation for deployments with particular requirements not met by built-in OpenAM functionality.

OpenAM comes with sample plugins that demonstrate how to customize policy evaluation. This chapter shows how to compile the samples, and how to configure OpenAM to use one of the plugins.

17.1. About the Sample Plugins

The OpenAM policy framework lets you build plugins to extend subjects, conditions, and response providers for policies, and also extend referrals for policy delegation. When you deploy OpenAM, you find Java code for sample policy evaluation plugins under *war-file-name*/source/com/sun/identity/samples/policy.

`SampleCondition.java`

Extends the `Condition` interface. Shows an implementation of a condition to base the policy decision on the length of the user name.

`SampleReferral.java`

Extends the `Referral` interface. Shows an implementation of a policy referral for delegation.

`SampleResponseProvider.java`

Extends the `ResponseProvider` interface. Shows an implementation of a response provider to send an attribute from the user profile with the response.

`SampleSubject.java`

Extends the `Subject` interface. Shows an implementation that defines the users to whom the policy applies, in this case all authenticated users.

Before including the plugins in OpenAM, you compile the four files, and package the classes into a `.jar` for deployment.

The sample policy evaluation code relies on two `.jar` files deployed with OpenAM.

`openam-core-10.1.0.jar`

When you deploy OpenAM, the file is *war-file-name*/WEB-INF/lib/openam-core-10.1.0.jar.

openam-shared-10.1.0.jar

When you deploy OpenAM, the file is *war-file-name*/WEB-INF/lib/openam-shared-10.1.0.jar.

```
$ cd /path/to/tomcat/webapps/openam/
$ mkdir classes
$ javac -d classes
  -classpath /path/to/tomcat/webapps/openam/WEB-INF/lib/openam-core-10.1.0.jar:
    /path/to/tomcat/webapps/openam/WEB-INF/lib/openam-shared-10.1.0.jar
    source/com/sun/identity/samples/policy/Sample*.java
$ cd classes/
$ jar cf ../policy-plugins.jar .
```

The .jar belongs under *war-file-name*/WEB-INF/lib/.

```
$ cp ../policy-plugins.jar /path/to/tomcat/webapps/openam/WEB-INF/lib
```

Alternatively, you can add individual classes under *war-file-name*/WEB-INF/classes/.

17.2. Configuring A Sample Policy Plugin

This section shows how to configure the sample custom policy condition that you built. Configuration involves defining the strings that describe the policy condition, and plugging the policy condition into the *iPlanetAMPolicyService*, and then restarting OpenAM in order to be able to add the condition to your policies.

The strings describing your plugin belong as properties values in two files, *war-file-name*/WEB-INF/classes/amPolicy.properties and *war-file-name*/WEB-INF/classes/amPolicyConfig.properties. To the former, add this property:

```
samplecondition-policy-name=Sample Condition
```

To the later, add this property:

```
x100=Sample Condition
```

Add the schema that describes your plugin to OpenAM.

```
$ ssoadm
  add-plugin-schema
  --adminid amadmin
  --password-file /tmp/pwd.txt
  --servicename iPlanetAMPolicyService
  --interfacename Condition
  --pluginname SampleCondition
  --i18nname amPolicy
  --i18nkey samplecondition-policy-name
```

Configuring A Sample Policy Plugin

```
--classname com.sun.identity.samples.policy.SampleCondition
```

Plug-in schema, Condition was added to service, iPlanetAMPolicyService.

Set the choice values of the schema to include your plugin with other policy conditions in the policy service.

```
$ ssoadm
set-attr-choicevals
--adminid amadmin
--password-file /tmp/pwd.txt
--servicename iPlanetAMPolicyConfigService
--schematype Organization
--attributename iplanet-am-policy-selected-conditions
--add
--choicevalues "x100=Sample Condition"
```

Choice Values were set.

Set the plugin policy condition as one of the default attributes of the policy service.

```
$ ssoadm
add-attr-defs
--adminid amadmin
--password-file /tmp/pwd.txt
--servicename iPlanetAMPolicyConfigService
--schematype Organization
--attributevalues "iplanet-am-policy-selected-conditions=Sample Condition"
```

Schema attribute defaults were added.

After completing configuration, restart OpenAM or the web application container.

```
$ /etc/init.d/tomcat stop
Password:
Using CATALINA_BASE:   /path/to/tomcat
Using CATALINA_HOME:   /path/to/tomcat
Using CATALINA_TMPDIR: /path/to/tomcat/temp
Using JRE_HOME:        /path/to/jdk1.6/jre
Using CLASSPATH:       /path/to/tomcat/bin/bootstrap.jar:
                        /path/to/tomcat/bin/tomcat-juli.jar
$ /etc/init.d/tomcat start
Password:
Using CATALINA_BASE:   /path/to/tomcat
Using CATALINA_HOME:   /path/to/tomcat
Using CATALINA_TMPDIR: /path/to/tomcat/temp
Using JRE_HOME:        /path/to/jdk1.6/jre
Using CLASSPATH:       /path/to/tomcat/bin/bootstrap.jar:
                        /path/to/tomcat/bin/tomcat-juli.jar
```

In OpenAM console, browse to Access Control > *Realm Name* > Policies > *Policy Name* > Conditions > New... Notice in the list of conditions that you can now apply your Sample Condition.

Configuring A Sample Policy Plugin

Step 1 of 2: Select Condition Type

- * Type:
- ☐ Active Session Time
 - ☐ Authentication by Module Chain
 - ☐ Authentication by Module Instance
 - ☐ Authentication Level (greater than or equal to)
 - ☐ Authentication Level (less than or equal to)
 - ☐ Authentication to a Realm
 - ☐ Current Session Properties
 - ☐ Identity Membership
 - ☐ IP Address/DNS Name
 - ☐ LDAP Filter Condition
 - ☐ Resource/Environment/IP Address
 - ☒ Sample Condition
 - ☐ Time (day, date, time, and timezone)

Chapter 18. Customizing Identity Data Storage

OpenAM maps user and group identities into a realm using data stores. An OpenAM data store relies on a Java identity repository (IdRepo) plugin to implement interaction with the identity repository where the users and groups are stored.

18.1. About the Identity Repository Plugin

This chapter describes how to create a custom identity repository plugin. OpenAM includes built-in support for LDAP and JDBC identity repositories. For most deployments, you therefore do not need to create your own custom identity repository plugin. Only create custom identity repository plugins for deployments with particular requirements not met by built-in OpenAM functionality.

Tip

Before creating your own identity repository plugin, start by reading the OpenAM source code for the FilesRepo or DatabaseRepo plugins under `com.sun.identity.idm.plugins`.

18.1.1. IdRepo Inheritance

Your identity repository plugin class must extend the `com.sun.identity.idm.IdRepo` abstract class, and must include a constructor method that takes no arguments.

18.1.2. IdRepo Lifecycle

When OpenAM instantiates your IdRepo plugin, it calls the `initialize()` method.

```
public void initialize(Map configParams)
```

The `configParams` are service configuration parameters for the realm where the IdRepo plugin is configured. The `configParams` normally serve to set up communication with the underlying identity data store. OpenAM calls the `initialize()` method once, and considers the identity repository ready for use.

If you encounter errors or exceptions during initialization, catch and store them in your plugin for use later when OpenAM calls other plugin methods.

After initialization, OpenAM calls the `addListener()` and `removeListener()` methods to register listeners that inform OpenAM client code of changes to identities managed by your IdRepo.

```
public int addListener(SSOToken token, IdRepoListener listener)
public void removeListener()
```

You must handle listener registration in your IdRepo plugin, and also return events to OpenAM through the IdRepoListener.

When stopping, OpenAM calls your IdRepo plugin shutdown() method.

```
public void shutdown()
```

You are not required to implement shutdown() unless your IdRepo plugin has shut down work of its own to do, such as close connections to the underlying identity data store.

18.1.3. IdRepo Plugin Capabilities

Your IdRepo plugin provides OpenAM with a generic means to manage subjects—including users and groups but also special types such as roles, realms, and agents—and to create, read, update, delete, and search subjects. In order for OpenAM to determine your plugin's capabilities, it calls the methods described in this section.

```
public Set getSupportedTypes()
```

The getSupportedTypes() method returns a set of IdType objects, such as IdType.USER and IdType.GROUP. You can either hard-code the supported types into your plugin, or make them configurable through the IdRepo service.

```
public Set getSupportedOperations(IdType type)
```

The getSupportedOperations() method returns a set of IdOperation objects, such as IdOperation.CREATE and IdOperation.EDIT. You can also either hard-code these, or make them configurable.

```
public boolean supportsAuthentication()
```

The supportsAuthentication() method returns true if your plugin supports the authenticate() method.

18.2. Identity Repository Plugin Implementation

Your IdRepo plugin implements operational methods depending on what you support. These methods perform the operations in your data store.

Create

OpenAM calls create() to provision a new identity in the repository, where name is the new identity's name, and attrMap holds the attributes names and values.

```
public String create(SSOToken token, IdType type, String name, Map attrMap)
    throws IdRepoException, SSOException
```

Read

OpenAM calls the following methods to retrieve subjects in the identity repository, and to check account activity. If your data store does not support binary attributes, return an empty Map for `getBinaryAttributes()`.

```
public boolean isExists(
    SSOToken token,
    IdType type,
    String name
) throws IdRepoException, SSOException

public boolean isActive(
    SSOToken token,
    IdType type,
    String name
) throws IdRepoException, SSOException

public Map getAttributes(
    SSOToken token,
    IdType type,
    String name
) throws IdRepoException, SSOException

public Map getAttributes(
    SSOToken token,
    IdType type,
    String name,
    Set attrNames
) throws IdRepoException, SSOException

public Map getBinaryAttributes(
    SSOToken token,
    IdType type,
    String name,
    Set attrNames
) throws IdRepoException, SSOException

public RepoSearchResults search(
    SSOToken token,
    IdType type,
    String pattern,
    Map avPairs,
    boolean recursive,
    int maxResults,
    int maxTime,
    Set returnAttrs
) throws IdRepoException, SSOException

public RepoSearchResults search(
    SSOToken token,
    IdType type,
    String pattern,
    int maxTime,
    int maxResults,
    Set returnAttrs,
    boolean returnAllAttrs,
    int filterOp,
```

Identity Repository Plugin Implementation

```
Map avPairs,  
  boolean recursive  
) throws IdRepoException, SS0Exception
```

Edit

OpenAM calls the following methods to update a subject in the identity repository.

```
public void setAttributes(  
    SS0Token token,  
    IdType type,  
    String name,  
    Map attributes,  
    boolean isAdd  
) throws IdRepoException, SS0Exception  
  
public void setBinaryAttributes(  
    SS0Token token,  
    IdType type,  
    String name,  
    Map attributes,  
    boolean isAdd  
) throws IdRepoException, SS0Exception  
  
public void removeAttributes(  
    SS0Token token,  
    IdType type,  
    String name,  
    Set attrNames  
) throws IdRepoException, SS0Exception  
  
public void modifyMemberShip(  
    SS0Token token,  
    IdType type,  
    String name,  
    Set members,  
    IdType membersType,  
    int operation  
) throws IdRepoException, SS0Exception  
  
public void setActiveStatus(  
    SS0Token token,  
    IdType type,  
    String name,  
    boolean active  
)
```

Authenticate

OpenAM calls `authenticate()` with the credentials from the DataStore authentication module.

```
public boolean authenticate(Callback[] credentials)  
    throws IdRepoException, AuthLoginException
```

Delete

The `delete()` method removes the subject from the identity repository. The name specifies the subject.

```
public void delete(SSOToken token, IdType type, String name)
    throws IdRepoException, SSOException
```

Service

The `IdOperation.SERVICE` operation is rarely used in recent OpenAM deployments.

18.3. Identity Repository Plugin Deployment

Your `IdRepo` plugin must link to `amserver.jar`, which when you deploy OpenAM is `war-file-name/WEB-INF/lib/amserver.jar`.

You can either package your plugin as a `.jar`, and then add it to `war-file-name/WEB-INF/lib/`, or add the classes under `war-file-name/WEB-INF/classes/`.

To register your plugin with OpenAM, you add a `SubSchema` to the `sunIdentityRepositoryService` using the **ssoadm** command. First, you create the `SubSchema` document having the following structure.

```
<SubSchema i18nKey="x4000" inheritance="multiple" maintainPriority="no"
    name="CustomRepo" supportsApplicableOrganization="no" validate="yes">
  <AttributeSchema cosQualifier="default" isSearchable="no"
    name="RequiredValueValidator" syntax="string"
    type="validator" >
    <DefaultValues>
      <Value>com.sun.identity.sm.RequiredValueValidator</Value>
    </DefaultValues>
  </AttributeSchema>
  <AttributeSchema any="required" cosQualifier="default"
    i18nKey="x4001" isSearchable="no"
    name="sunIdRepoClass" syntax="string"
    type="single" validator="RequiredValueValidator" >
    <DefaultValues>
      <Value>org.test.CustomRepo</Value>
    </DefaultValues>
  </AttributeSchema>
  <AttributeSchema cosQualifier="default" i18nKey="x4002" isSearchable="no"
    name="sunIdRepoAttributeMapping" syntax="string" type="List">
    <DefaultValues>
      <Value></Value>
    </DefaultValues>
  </AttributeSchema>
</SubSchema>
```

Also include the `AttributeSchema` required to configure your `IdRepo` plugin.

Notice the `i18nKey` attributes on `SubSchema` elements. The `i18nKey` attribute values correspond to properties in the `amIdRepoService.properties` file, stored under `war-file-name/WEB-INF/classes/`. OpenAM console displays the label for the configuration user interface that it retrieves from the value of the `i18nKey` property in the `amIdRepoService.properties` file.

Register your plugin using the **ssoadm** command after copy the files into place.

```
$ ssoadm
add-sub-schema
--adminid amadmin
--password-file /tmp/pwd.txt
--servicename sunIdentityRepositoryService
--schematype Organization
--filename customIdRepo.xml
--subschemaname CustomRepo
```

Login to OpenAM console as administrator, then then Browse to Access Control > *Realm Name* > Data Stores. In the Data Stores table, click New... to create a Data Store corresponding to your custom IdRepo plugin. In the first screen of the wizard, name the Data Store and select the type corresponding to your plugin. In the second screen of the wizard, add the configuration for your plugin.

After creating the Data Store, create a new subject in the realm to check that your plugin works as expected. You can do this under Access Control > *Realm Name* > Subjects.

If your plugin supports authentication, then users should now be able to authenticate using the DataStore module for the realm.

```
http://openam.example.com:8080/openam/UI/Login?realm=test&module=DataStore
```
